The Columbus Hospital, Great Falls, Mont., Plumbing and Heating Contractors, Pinski Bros. Equipped with Crane Plumbing Materials

Sit in with the board of other hospitals

The best way to insure against making any mistakes in buying plumbing equipment for hospitals, clinics, or dispensaries is to let the experience of other building boards guide you.

When you make a survey, you will, in all likelihood, be impressed by the imposing number of modern institutions that are Crane equipped. Even more so by the fact that these institutions, whether

they are large or small, offer real endorsements of Crane quality.

Certainly such a method of allowing the experience of other boards to guide you provides the safest course. Then to fit their experience to your individual needs, draw on the knowledge of the Crane hospital service. Collaborating with you, this service will lay out a plumbing system that will exactly fit your requirements.

THE STEADY SCIENTIFIC PROGRESS OF THE BELL LABORATORIES SHOWS IN THE EVER-INCREASING QUALITY AND SCOPE OF YOUR TELEPHONE SERVICE

To clear all barriers for the human voice

An Advertisement of the American Telephone and Telegraph Company

BELL TELEPHONE LABORATORIES, Incorporated, is the scene of a progressive conquest of natural forces that aims to let you speak clearly, quickly and cheaply to any one, anywhere in the land and even to distant countries. More than 5000 scientists and assistants are busy there and elsewhere in the Bell System studying the problems of sound transmission. Its work is the growing foundation of the telephone art; and it has, besides, helped to make possible the radio, sound pictures and special apparatus for the medical profession.

Among its achievements are the underground cables which make city telephone service possible, better and faster long distance service, service to ships at sea, and to millions of telephones beyond the seas.

The steady scientific progress of the Bell Laboratories shows in the ever-increasing quality and scope of your telephone service. Its new developments in every type of equipment clarify and speed up your telephone talks and give you more and better service at low rates. Every advance it makes is available throughout the Bell System.

The Bell System is an American institution owned by more than 500,000 stockholders. It places before you the benefits of its technical achievements and the co-ordinated efforts of more than 400,000 trained workers. It accepts its responsibility to further the development and welfare of the nation by furnishing the public the best of telephone service at the least cost consistent with financial safety.

NOTHING LESS THAN SPENCER PRECISION SLIDING MICROTOME No. 860

Statement

made by a Professor in one of America's greatest universities. He had one of these microtomes and bought two more.

- I. It is a precision Microtome, feeds automatically and cuts to two microns.
- II. It cuts sections of ACCURATE thickness, one after another of the same thickness, not only of the usual soft tissue but wood sections and hard tissue usually found very difficult to cut on any microtome.
- III. It will cut sections of large size $3\frac{1}{2}$ inches—one after another until $1\frac{1}{2}$ " of the object is consumed without necessity of raising the object and resetting the feed for further sectioning.
- V. It is built of heavy frame 14" long and 7" high, carrying a bed for the sliding block of 16" length; a knife support holds the knife rigidly in one plane while moving to and fro. A substantial ball and socket object clamp is fed upward by a feeding mechanism of unvarying accuracy.

The Speed merchant *closes for repairs*

DRIVE . . . DRIVE . . . DRIVE! That's his middle name. Success is his goal, and health isn't even a second thought. Work done is work done, even if it's done on the false energy of stimulants. That is the short-sighted philosophy of this "far-sighted" businessman. And now, run-down and all-in, he takes time out for repairs, takes a disappointing inventory of health.

If you advise him to give up caffein-containing beverages, you know how he'll protest, perhaps not to you, but to himself. You know what a struggle it will be for him. For he's a creature of habit, and the caffein habit is a particular pet of his.

But Postum will make your task easier—and his. For Postum offers all the cheering warmth, all the satisfying goodness, all the tempting fragrance of forbidden caffein-containing drinks. It makes parting with these forbidden drinks so much easier. Yet Postum is made only from whole wheat and bran, roasted to a turn, and slightly sweetened. It is so good that two and a half million families drink it regularly.

Instant Postum made-with-hot-milk is a most valuable addition to the diet in cases of under-nourishment. And it is so delicious that even patients who do not like milk drink it eagerly. Postum is a product of General Foods Corporation.

GENERAL FOODS DEPT. PV-131

Battle Creek, Michigan

We will be glad to send the physician who addresses us a special gift package containing a full-size package of Instant Postum, together with samples of Grape-Nuts, Post Toasties, Whole Bran, and Post's Bran Flakes. If you live in Canada, address General Foods, Limited, Dept. PV-131, Sterling Tower, Toronto 2, Ontario.

SQUIBB EPHEDS

A new and convenient Ephedrine preparation for the relief of colds

EPHEDRINE, an alkaloid prepared from the Chinese drug Ma Huang, has in recent years been recognized as a particularly effective drug for the relief of head colds.

Squibb now provides ephedrine compound containing an oil-soluble ephedrine salt in an oily base and marketed in a new, unique form under the distinctive name "Epheds."

Squibb Epheds are long-necked, flexible gelatin capsules for nasal application. Each capsule contains 8 minims of a 1/2% solution of ephedrine—in combination with aromatics and antiseptics.

Relief from congestion is promptly obtained when Epheds are used and the effect lasts for hours. Epheds provide a simple, convenient means of applying ephedrine into the nose without waste or the use of an atomizer.

Supplied in easy-to-carry boxes of one dozen, for use at home or when traveling.

Quick bacteria counts

THE FROST METHOD IS *faster*

FOR FIELD OR LABORATORY

WHEREVER time saving is important the Frost Little Plate method is recognized by bacteriologists as the fastest simple way of making an accurate count of the bacteria in milk.

The constantly growing demand for this equipment since the publication of the method in 1921 is due to the fact that, while reducing the total time required for the test to, at the most, a third of that necessary in the older plate methods, there is no loss of accuracy and no need for more specialized technique than is called for by previous standard counting practices.

There is also in the Frost method the additional advantage of economy occasioned by the substitution of microscope slides for Petri dishes and by the much smaller quantity of medium used.

For complete information on this equipment and a detailed discussion of the method ask for our free Bulletin 97-G.

*It is characteristic of most babies fed on milk
properly modified with Mellin's Food
that they are not troubled with constipation*

Mellin's Food

A Milk Modifier

Constipation in Infancy

CONSTIPATION in infancy is worthy of the physician's careful attention, for this symptom is often an indication of some fault in the diet which should be corrected, not only as a measure of relief from this annoying condition but to obtain a better-balanced food mixture.

Continued constipation is very good evidence that the food elements entering into the making of the baby's diet are not well suited to an infant's digestion or are not in exactly the right proportion, and such a situation may easily be responsible for a slow gain in weight, restless nights and a fretful, uncomfortable baby. Progress in general is likely to be more satisfactory if the contents of the lower bowel are eliminated at fairly regular daily intervals. Therefore, it is consistent with good treatment to exercise every effort to promote normal stools.

ERRORS in diet causing constipation may be determined by observing the color, odor and character of the stools, and by noting the general condition and progress of the baby patient. These points of recognition of symptoms are taken up in a pamphlet which should prove very helpful in readjusting the diet to overcome constipation. *A copy will be sent to physicians upon request.*

FOR VALUE RECEIVED

A GREAT MANY PEOPLE will tell you that the biggest single service that five cents can buy today is a local telephone call. Without question, it is big value . . . and value that steadily grows as new telephones come into your neighborhood.

There are times when telephone service is priceless . . . when the ability to call instantly a doctor, a policeman, or the fire department could not be measured in terms of money.

But it is not alone the emergencies that give the telephone its value. There are the common-places of every-day conversation . . . in the home, the shop, the office . . . whenever you wish two-way communication with any one, almost anywhere.

The telephone has become such

an every-day, matter-of-fact convenience—like running water and electricity—that it is natural to take it for granted. It is well to pause occasionally and consider the nation-wide organization of men, money, and materials that makes this vital service possible, and at such low cost.

Here is a system of the public, for the public . . . run on the barest margin of profit consistent with service, security, and expansion. A service that grows as the community grows . . . placing within the reach of an increasing number the means to talk back and forth with people in the next block, the next county, a distant state, a foreign country, or on a ship at sea!

No other money that you spend can bring you more actual value.

SPENCER BINOCULAR MICROSCOPE
No. 4ML-H
WITH
NEW INCLINOCULAR

Designed for comfort and efficiency, especially where microscope stage must be horizontal as in examination of liquids. It is an inclined eyepiece binocular body taking the place of regular binocular body.

The angle of inclination is suited to the comfort of the observer. No compensating lenses are necessary because of added tube length. It has many advantageous features.

This microscope makes an ideal outfit for medical research work.

Send for New Bulletin M-45.

TIME OUT *for the* DYNAMO

HE's been a "human dynamo," a fiend for work. He's kept going long after others had quit. And always his partner has been the false energy of stimulants. And at last, nature, driven to the limit, has called time out for the dynamo. So he turns to you, asking for the health he has tossed away.

And if you find that it is advisable for him to give up caffeine, you know what bad news that is to him. For that caffeine habit is an old standby of his, a pleasant companion, a cherished one. And he hates to part with it.

But there's help for him in Postum. For Postum will give him all the cheering warmth, all the goodness, all the full-bodied flavor of caffeine-containing beverages. Postum is made from whole wheat and bran, roasted to a turn and slightly sweetened. It is so good, so good in its own right, that two and a half million families serve it regularly.

Many physicians have found that Instant Postum made-with-hot-milk is a valuable addition to the diet in cases of under-nourishment. It is strengthening and nourishing and particularly pleasing to those who do not like milk. Postum is a product of General Foods Corporation.

Nature takes a deferred payment

THEY probably come to you often . . . those people who have bought success with borrowed energy, little dreaming that nature would ask an accounting. They come to you, victims of heedless living, slaves to stimulants. They come to you run down and overworked, wondering why this has had to happen to them.

And if, among other things, you suggest that they give up caffein, you know what a struggle is in the offing. For the caffein habit is a husky one, deep-rooted, and very pleasant. It's a habit that clings and clings, a veritable barnacle among habits.

But there's real aid in Postum. For Postum helps patients forget caffein-containing beverages. Postum is rich, full-bodied and appetizing. It provides all the cheering warmth, all the fragrant aroma, all the goodness of drinks containing caffein. Postum is made from whole wheat and bran, roasted to a turn, and slightly sweetened. Two and a half million families drink it regularly—eagerly.

In cases of under-nourishment, Instant Postum made-with-hot-milk is a valuable addition to the diet. It is strengthening and soothing and far more pleasant to drink than milk alone. Postum is a product of General Foods Corporation. © 1931, G. F. CORP.

AMNIOTIN

A Potent Preparation of . . .
Ovarian FOLLICULAR Hormone

Amniotin is the only commercial preparation of the ovarian follicular hormone which is tested by inducing menstruation in spayed monkeys and assayed on spayed rats by the original Allen-Doisy method. It is standardized and labelled in terms of the original Allen-Doisy unit so that it can be administered in accurate dosage.

Amniotin is indicated in the treatment of disorders referable to hypofunction of the ovarian follicular hormone. It relieves the symptoms of the menopause, natural and artificial, and corrects primary amenorrhea (absence of menstruation), hypomenorrhea (scanty menstruation) and oligomenorrhea (infrequent menstruation) when due to a deficiency of the ovarian hormone.

A Safer World for Babies

1 No baby, artificially fed, need ever be ill a single day from any harmful germ carried in his milk.

2 No baby need ever suffer discomfort or digestive upset because of the hard curds of cow's milk.

3 No baby need ever be given skimmed or partly skimmed milk because of trouble in digesting the fat in cow's milk.

4 No doubt or question need ever arise about the safety and wholesomeness of the milk supply for any baby under your care.

When babies are given Evaporated Milk those things do not happen. And the reasons are simple and plain. Sterilized in sealed containers, Evaporated Milk is surely free from harmful germs. Because of the effect of sterilization, the curds that form in the course of digestion of Evaporated Milk are soft and flocculent.

Because Evaporated Milk is homogenized, the fat globules are as small as those in human milk—the fat readily assimilable. Evaporated Milk, everywhere, has those superior qualities. It is everywhere available.

Experience with hundreds of babies, by eminent specialists, has demonstrated the wholesomeness of this form of milk for infants. Sturdy growth, and freedom from digestive disturbance and illness has been the rule for babies fed on Evaporated Milk.

We'll be glad to send you, free of charge, reports by the specialists—reprints of articles from the leading medical journals. Fill out the coupon.

Continued on page vi

Ulcer

(No-residue diet)

Mellin's Food 4 tablespoonfuls
Water 1 cupful

Dissolve the Mellin's Food in the water by stirring briskly (no cooking required). To be given cold or warm, not hot.

(Low-residue diet)

Mellin's Food 6 tablespoonfuls
Whole Milk 10 fluidounces
Water 4 fluidounces

Dissolve the Mellin's Food in the water and then add the milk (no cooking required). Allow the mixture to stand in a cool place for 2 hours, after which a cupful may be given every 2 or 3 hours, or at such intervals as the physician directs.

In serious disturbances of the stomach or intestine and particularly where gastric or duodenal ulcer is present or suspected, it would appear that nourishment capable of rapid and complete assimilation as set forth in the first mixture, and a low-residue diet as prepared from the second formula, is much to be desired as a part of the treatment, and the above suggestions are offered as a means to this end.

Distress from hyperacidity is promptly relieved by giving the first-mentioned mixture. A small quantity of Mellin's Food, dry, placed upon the tongue from time to time, permitted to remain in the mouth until dissolved and then swallowed, will also give quick relief. This use of dry Mellin's Food is especially recommended in persistent vomiting.

Mellin's Food Company,

Boston, Mass.

PENNIES FOR WINGS

DAY in and day out you take wings by talking over your telephone . . . with friends . . . the grocer . . . the doctor . . . a relative hundreds of miles away . . . and every month you get a bill for this service.

Perhaps a single call made during this period has been worth more to you in time, money or convenience than the whole amount of your bill. But the telephone company makes its charge—not on any such basis—but on what it costs to give the best possible service to its customers.

The Bell System has voluntarily taken the position that the telephone business is a public trust. Its policy is to give the best possible service at the least cost consistent with financial safety.

The more telephone subscribers

there are, the more valuable telephone service becomes to each subscriber. Unlike most other businesses, the telephone industry does not enjoy reduced costs as the number of customers increases. On the contrary, the trend is upward. To offset this, the American Telephone and Telegraph Company takes advantage of every scientific advance and aid to efficiency which can possibly reduce service costs—and these savings are used for the benefit of the subscriber.

The twenty-four Associated Companies in the Bell System are pledged to this ideal . . . to give constantly better telephone service at the lowest possible rates . . . to reduce, by every means in their power, the number of pennies that you pay for wings.

furnished with our compliments in your own medicine cabinet
will soon convince you that

MERCUROCHROME---220 SOLUBLE

(dibrom-oxymercuri-fluorescein)

IS THE

Logical Successor to Tincture of Iodine

FOR

First Aid Prophylactic and General Antiseptic Use

Mercurochrome stains as Iodin does, and it is the stain of Mercurochrome, as it is of Iodin, that shows just where and how effectively the germicide has been applied; it fixes the bactericidal agent in the field for a relatively permanent period which prolongs the asepsis or the sterilizing effect, and it provides for demonstrable penetration into the tissues beneath the superficial surfaces. Inasmuch as Mercurochrome is definitely proved an extremely efficient general antiseptic, it is only reasonable to consider it the successor to Iodin in this field, as it is free from the objectionable features of Iodin, for

MERCUROCHROME DOES NOT IRRITATE, BURN OR INJURE TISSUE

An ARMISTICE *with nature*

HIS BATTLE with nature is over—and he's lost. He's discovered that he can't keep going on the false energy of stimulants—can't drive himself when nerves and health protest—can't fight nature, and win. So he comes to you, asking you to draft the terms of an armistice, asking you for health.

If part of your advice to patients of this type is to give up caffein-containing drinks, you know that there's often a lot of fight left in them. For they love that deep-rooted habit. It's a pleasant one. It's been a constant companion.

Hundreds of physicians, however, have discovered that there's real help in Postum. For Postum offers all the goodness, all the cheering warmth, all the tempting fragrance of caffein-containing drinks—and it takes their place with surprising ease. Yet Postum is made only from whole wheat and bran, roasted to a turn and slightly sweetened. It is a mealtime favorite with two and a half million families.

Instant Postum made-with-hot-milk is a valuable addition to the diet in cases of under-nourishment. It is particularly acceptable when patients do not enjoy plain milk. Postum is a product of General Foods Corporation.

She overbid . . . *and Nature doubled!*

You know her type. She has energy to burn—apparently. She's always going to rest—but never does. She keeps going on the borrowed pep of stimulants . . . until one day she comes to you, run-down, spent, a bundle of nerves.

If part of your advice to her is "Give up caffein-containing drinks," you know how often her reaction is arched eyebrows, an unuttered protest. She may be willful about it. For she likes that forbidden beverage, likes the way it "picks her up." And she hates to part with it.

But you've a great ally in Postum. Postum has a way of telling her that caffein-containing drinks aren't so important to her after all. For Postum offers all the cheering warmth, the deliciousness, the appetizing fragrance of these drinks. Yet Postum is made only from whole wheat and bran, roasted to a turn and slightly sweetened. Two and a half million families drink it regularly.

In cases of under-nourishment, Instant Postum-made-with-hot-milk is a valuable addition to the diet. You will find it particularly helpful when patients do not like plain milk, for it is a most delicious drink. Postum is a product of General Foods Corporation.

Tetanus will soon reach its annual high peak

Tetanus is ever a constant danger when deep puncture wounds occur. During the summer, children and adults will again indulge in outdoor activity, and with consequent increased exposure to infection.

Every laceration or burn exposed to street dirt or garden soil may be followed by tetanus infection. Every precaution should be taken to prevent the development of tetanus.

Tetanus Antitoxin Squibb is high in potency, small in bulk and low in total solids, yet of a fluidity that permits rapid absorption. It is remarkably free from reaction-producing proteins. A prophylactic dose of Tetanus Antitoxin should be given whenever there is any possibility of infection.

Tetanus Antitoxin Squibb for prophylactic use is supplied in vials or syringes containing 1,500 units. Curative doses are marketed in syringes containing 5,000, 10,000 and 20,000 units.

For your Information

Some people have had the impression that the change in the size of the can of Evaporated Milk from 16 ounces to 14½ ounces was for the purpose of raising the price to consumers. Such was not the purpose, nor has it been the result.

The purpose of the reduction in the size of the can was to enable the package to be sold at a lower price than could be made on the 16-ounce can. That is now being done. The new size was fixed at 14½ ounces for the reason that this quantity of Evaporated Milk is closely comparable in food value to a full quart of milk of legal standard under the laws of practically every state in the Union.

One of the distinctive features of Evaporated Milk is its economy. The tall can should cost no more than 9 cents anywhere. It can be purchased in many places at 3 cans for 25 cents; in some places, even for less. Where economy is an item, as it is in so many instances these days, Evaporated Milk will be a great boon.

And with the point of economy you get these qualities everywhere:

- 1 Sure safety—complete freedom from any chance of harmful germs.
- 2 Uniform food content—every drop uniformly rich in all the food substances of whole milk.
- 3 More ready digestibility—the soft curds and the homogenized fat.

You can recommend Evaporated Milk, knowing that the milk is safe and wholesome—knowing, too, that you are helping to accomplish substantial saving. An extraordinary product, at the lowest possible price, is the purpose of the Evaporated Milk industry. That is its contribution to the public welfare.

MELLIN'S FOOD**4 level tablespoonfuls****WATER (boiled then cooled) 16 fluidounces**

for Summer Diarrhea

Further details in relation to this subject are set forth in a pamphlet entitled, "The Feeding of Infants in Diarrhea", and in our book, "Formulas for Infant Feeding". This literature will be sent to physicians upon request.

THE above formula provides a means of supplying the principal fuel utilized in the body for the production of heat and energy and furnishes immediately available nutrition well suited to protect the proteins of the body, to prevent rapid loss of weight, to resist the activity of putrefactive bacteria, and to favor a retention of fluids and salts in the body tissues.

While the condition of the baby will guide the physician in regard to the amount and intervals of feeding, the usual custom is to give one to three ounces every hour or two until the stools lessen in number and improve in character. The food mixture may then be gradually strengthened by substituting one ounce of skimmed milk for one ounce of water until the amount of skimmed milk is equal to the quantity of milk usually employed in normal conditions. Finally the fat of the milk may be gradually replaced, but as milk fat is likely to be digested with much difficulty after an attack of diarrhea it is good judgment to continue to leave out the cream until the baby has fully recovered.

SAVING MONEY

FOR TELEPHONE SUBSCRIBERS

DURING the past fifty-five years, the constant effort of the Bell System has been to provide efficient telephone service for all the people at the lowest possible price. There are many instances of substantial savings for subscribers.

Since the latter part of 1926 the reductions in long distance rates have been particularly marked. For example, a telephone call across the country from New York to San Francisco now costs \$9 instead of \$16.50. Reductions have also been made for lesser distances. As a result of these rate reductions, telephone users are now saving the substantial amount of \$20,000,000 annually.

You, as a telephone subscriber, are constantly receiving extra value

from your telephone—because the number of subscribers is increasing, and the more people you can reach by telephone, the more valuable it is to you.

Today, there are few things purchased by the family or by a business that give so much useful service at such low price as the telephone.

Every time you pick up the telephone you become part of a communication system that uses eighty million miles of wire and represents an investment of more than four thousand million dollars. Yet the cost of local service that puts you in direct personal touch with thousands or hundreds of thousands of people in your town or city is only a few cents a day.

When the "Iron man"

starts to rust

HE THINKS he's an "Iron man." Nature thinks he's a fool. And Nature is right. He's been borrowing false energy from stimulants, whipping nerves that cried for rest, working, working, working . . .

Now he has come to you, asking you to bring back the health he has squandered. Yet if part of your advice is "give up caffeine-containing beverages" he may demur. For he feels that caffeine is an old friend—and parting is extremely difficult.

In cases of this kind, Postum is a real help. For Postum, as

hundreds of physicians have discovered, has a way, a delightful way, of replacing drinks containing caffeine. And that is because Postum provides all the cheering warmth, all the rich, full-bodied goodness of these drinks. Yet Postum is made only from whole wheat and bran roasted to a delectable brown, and slightly sweetened. It is so good that two and a half million families drink it regularly.

When patients are undernourished, Instant Postum made-with-hot-milk is a valuable addition to the diet. It is soothing and strengthening and decidedly appetizing. Postum is a product of General Foods Corporation.

GENERAL FOODS, DEPT. PV-731, BATTLE CREEK, MICHIGAN

We will be glad to send the physician who addresses us a special gift package containing a full-size package of Instant Postum, together with samples of Grape-Nuts, Post Toasties, Whole Bran, and Post's Bran Flakes. If you live in Canada, address GENERAL FOODS, Limited, Dept. PV-731, Cobourg, Ontario.

Gentlemen Without Humor

TOO LATE they see they've been "kidding themselves." Too late they discover that this false energy they've borrowed from stimulants has taken its toll in health. And they come to you, asking you to mend their bodies, perhaps little realizing that they must first mend their ways.

If, as part of your advice to them, you suggest that they give up caffein-containing beverages, Postum may be a real help. For Postum is a delicious, cheering beverage that speeds and eases the departure of drinks containing caffein. It's a drink that gently relaxes the strong grip of habit—banishes caffein beverages with small regret.

Yet Postum is made only from whole wheat and bran, roasted to a turn and slightly sweetened. It is such a good drink that it is an old standby of two and a half million families.

Many physicians have found that Instant Postum made-with-hot-milk is a valuable help in cases of under-nourishment. Patients who don't like plain milk appreciate it especially, for it makes milk taste so much better. Postum is a product of General Foods Corporation.

Dr. Edward Jenner, 1744-1823

Parliament Paid Him £30,000

IN 1796 Dr. Edward Jenner performed his first smallpox vaccination experiments. So successful was his work and so serious the situation he corrected that Parliament awarded him £30,000 sterling for his discovery.

The effectiveness of vaccination for prevention of smallpox is attested by the constantly decreasing death rate from this loathsome disease. In Germany, in 1874, vaccination and revaccination became compulsory by law and since that time smallpox has ceased to be an epidemic disease. In fact only 1,115 deaths have occurred in 30 years.

In this country vaccination is not compulsory in several states and only the vigilance of health officers is maintaining a low incidence of smallpox.

Smallpox Vaccine Squibb is a highly potent, glycerinized vaccine. It is prepared under strictest aseptic conditions and is not released for the market until it has been shown to be capable of giving 100% active "takes" in previously unprotected individuals.

Smallpox Vaccine Squibb is dispensed in packages of 1, 5, and 10 capillary tubes supplied with a rubber bulb and sterile needle for each vaccination.

NOTE:—To ensure proper "takes," Smallpox Vaccine should be kept in refrigerator as its potency is quickly destroyed at room temperature.

The milk supply for summer

When there's question about the milk supply in the summer time, consider how Evaporated Milk will help in any of the following circumstances:

1 The quality of ordinary milk is sometimes affected by summer weather. That doesn't happen with Evaporated Milk. Completely sterile in a sealed, air-tight container, no condition of weather can cause, or develop, any contamination of Evaporated Milk.

2 People want to make trips. No matter where they go they can have a milk supply that they know will be safe and wholesome—for the baby, for children, or for adults. Evaporated Milk can be had everywhere. To the most remote camp in the deepest woods a supply for the whole summer can be taken along. It needs no ice to keep it, and the last can used will be as fresh and sweet as the first.

3 When children's appetites are dulled by the hot weather, delicious milk-drinks can be made with Evaporated Milk and fruit juices. The milk blends perfectly with any of the fruit juices—tomato, orange, or grape, fresh or canned or bottled—to make wonderfully refreshing drinks. They'll tempt and stimulate the appetite. They're good for everybody.

Let us send you recipes for making these milk-drinks. Let us send you also an interesting book "Eating for Efficiency"—as many copies as you'd like to have. It will help you to advise people how they can make better food for every member of the family.

Accepted!

Now let this seal be your guide
to abundant Vitamin B

INVESTIGATIONS in chronic vitamin B deficiencies have stressed the importance of constantly restoring this important element to the body. This is especially true of growing children; and it is also exceedingly valuable to the diets of pregnant or nursing mothers because of the undoubted salutary effect of a sufficiency of vitamin B on lactation.

BEMAX is entire cereal embryo (germ), one of the richest natural sources of vitamin B. It is carefully tested and standardized for vitamin B content, and assays at least 560 units per ounce by the Sherman method. *Thorough stabilization* insures its keeping qualities at all times.

BEMAX is a palatable, convenient, and easily digested supplement to the diet, particularly when there is a suspected insufficiency of vitamin B; as in asthenic and debilitated states,

in convalescence, malnutrition, and many gastro-intestinal disturbances.

A tablespoonful, daily, for the adult, or one to two teaspoons for the child, furnishes an abundance of the B vitamin, together with some vitamins A and E, and considerable mineral value. It does not require cooking, and blends well with many foods such as milk, soups, fruits, salads, desserts, etc. . . . Try BEMAX yourself, or recommend it in your next case of suspected vitamin B deficiency. Generous samples will be

sent to interested physicians, and interesting literature on vitamin B deficiencies is available on request.

THE TELEPHONE HAS LIVING IDEALS

THE Bell System is chiefly people. There is four billion dollars' worth of telephone buildings and equipment but what makes these dead things live is the organization, the skill and the ideals of the people who operate this vast plant.

The System's ideals of service are reflected through the employees in 24 regional operating companies. Each company is adapted to the needs of its particular area. Each takes advantage of the improvements developed by the 5000 members of the Bell Laboratories staff. Each avails itself of the production economies of Western Electric, which manufactures equipment of the highest quality for the whole System. Each makes use of the general and technical staff work

done by American Telephone and Telegraph.

The spirit of the people comprising this organization is also shown in the attitude of the System toward its business. Its policy is to pay a reasonable dividend to stockholders; to use all other earnings to improve and widen the service.

There are more than 600,000 American Telephone and Telegraph Company stockholders . . . and no one person owns so much as one per cent of the stock.

The ideals of the Bell System are working in your interest every time you use the telephone. Through them, you get better and better service and constantly growing value for your money.

The following mixture is recommended as a temporary diet in intestinal disturbances of infants commonly spoken of as summer diarrhea:

MELLIN'S FOOD 4 level tablespoonfuls
WATER (boiled, then cooled) 16 fluidounces

Weight in grams of food elements in each ounce of the above mixture:

PROTEINS	0.176 Grams
MALTOSE	1.002 Grams
DEXTRINS	0.352 Grams
SALTS	0.073 Grams

Summer Diarrhea

Individual conditions will guide the physician in regard to the amount to be given at each feeding and the intervals of feeding, and naturally the intake per day will be thus influenced. Assuming, however, that the above-stated amount (16 fluidounces) is administered during the full twenty-four hours, the actual daily intake of food elements would be as follows:

PROTEINS	2.82 Grams
CARBOHYDRATES { Maltose 16.03 Grams }	21.66 Grams
{ Dextrins 5.63 Grams }	
SALTS	1.17 Grams

This gives a total of 25.65 grams of nourishment that is readily digestible and available for immediate assimilation. The mixture also contributes 101 Calories for the generation of heat and energy.

The above accurate examination of the quantity and quality of food elements in the suggested mixture is set forth in order that physicians may determine to their own satisfaction the value of this means of replenishing elements withdrawn from the infant's organism as one of the results of frequent bowel movements.

No More Mental Crutches

YOU probably come in contact with them often . . . fagged-out men struggling through life with the aid of mental crutches . . . with the aid of stimulants. Tired men who come to you virtually broken, having exhausted nature's reserve energy and nature's patience.

And if you've told them to forget stimulants, told them to forget caffeine-containing beverages, the sequel is an old, old story to you. Habit clashing with orders. Good judgment fighting deep ruts. Will-power struggling uphill.

But, where the caffeine-habit is concerned, there's real aid in Postum, as so many physicians have discovered. For Postum is a cheering drink. A flavorsome, steaming beverage, with an aroma that tempts and conquers.

Yet Postum is made only from whole wheat and bran, roasted to a turn and slightly sweet-

ened. Two and a half million families like it so well they drink it regularly.

Instant Postum made-with-hot-milk is a most valuable addition to the diet in cases of under-nourishment. People who don't like plain milk drink it eagerly when it is disguised in this delightful way. Postum is a product of General Foods Corporation.

GENERAL FOODS, DEPT. PV-1031
BATTLE CREEK, MICHIGAN

We will be glad to send the physician who addresses us a special gift package containing a full-size package of Instant Postum, together with samples of Grape-Nuts, Post Toasties, Whole Bran, and Post's Bran Flakes. If you live in Canada, address General Foods, Limited, Dept. PV-1031, Cobourg, Ontario.

Partial Vitamin B Deficiencies Are More Prevalent Than Is Commonly Supposed...

WORKERS in nutritional research, McCollum, Hoobler, Sure, Cowgill, Sherman and Eddy, among others, have noted a definite relation between a lack of sufficient vitamin B in the diet and such common conditions as loss of appetite, malnutrition and impaired assimilation of food, retardation of growth and development, derangements of gastro-intestinal function (including constipation), and general impairment of physical condition and resistance to disease.

Few foods are really rich in this necessary vitamin; examination of the ordinary diet shows it often present in but small amount. The very frequent improvement in health which follows the addition of vitamin-B-rich foods, in both infants and adults, is corroboratory evidence that "run down" conditions, constipation, and other chronic gastro-intestinal disorders are often attributable to a chronic *partial* deficiency of vitamin B.

BEMAX supplies the diet with abundant vitamin B. It is entire cereal germ, thoroughly stabilized against deterioration, and standardized

as to vitamin B content, assaying at least 560 units vitamin B to the ounce (Sherman method).

It is palatable, economical, completely digestible; its content of crude fiber is negligible.

A tablespoonful a day for adults, or a teaspoon or two a day for children, is *nutritional insurance*; it affords protection against the insidiously harmful effects of deficiency.

Sprinkle BEMAX on cereals, fruits, or salads; mix it with milk or soup. Remember that vitamin B is not stored in the body but must be renewed daily. Feed it regularly for a month or more and note results.

Interesting literature on vitamin B deficiencies will be gladly sent on request.

These Squibb Antitoxins will meet your requirements

When the occasion demands, whether it be a case of diphtheria, erysipelas, scarlet fever or tetanus infection, successful biologic therapy depends on the use of highly potent, refined and concentrated products. Squibb Antitoxins have invariably withstood the test of clinical experience. They are small in bulk and low in total solids, hence of sufficient fluidity to promote rapid absorption. The incidence of serum sickness is greatly reduced because their method of preparation assures the removal of the offending reaction-producing substances to a marked degree.

All Squibb Antitoxins are accepted by the Council on Pharmacy and Chemistry of the A. M. A.

SQUIBB DIPHTHERIA PRODUCTS

Diphtheria Antitoxin Squibb—For prophylaxis and treatment.

Diphtheria Toxin for Schick Test—To determine susceptibility to diphtheria. Now available in a form already diluted, ready for use.

Diphtheria Toxin-Antitoxin Mixture—For active immunization of susceptible persons against diphtheria. Prepared with concentrated diphtheria antitoxin from sheep.

Diphtheria Toxoid Squibb (Anatoxin Ramon)—A very effective product for active immunization against diphtheria.

TETANUS ANTITOXIN SQUIBB

For prophylactic use it is supplied in vials or syringes containing 1,500 units. For curative use, it is marketed in syringes containing 5,000, 10,000 and 20,000 units.

SQUIBB AUTHORIZED SCARLET FEVER PRODUCTS

Scarlet Fever Streptococcus Antitoxin Squibb—For early treatment of Scarlet Fever.

Scarlet Fever Streptococcus Antitoxin Squibb—For Blanching Test.

Scarlet Fever Streptococcus Toxin Squibb—For Dick Test.

Scarlet Fever Streptococcus Toxin Squibb—For active immunization against Scarlet Fever.

ERYSIPELAS ANTITOXIN SQUIBB

Erysipelas Streptococcus Antitoxin Squibb markedly reduces the mortality rate and the period of disability. Prepared according to principles developed by Dr. Konrad E. Birkhaug. Distributed in concentrated form in syringes containing one average therapeutic dose.

REACH FOR YOUR TELEPHONE AND TAKE COMMAND

You need only pick up your telephone to control millions of dollars' worth of property . . . a thousand yards or a thousand miles of wire . . . five thousand or five million dollars' worth of equipment . . . a few or many of the Bell System's hundreds of thousands of trained workers.

What you get from your telephone depends on your wish of this or any moment.

Few things you buy can so exactly fit your needs. Telephone service is made to your order for each call . . . and the telephone becomes an extension of your voice and personality for whatever purpose you choose. All of the System's plant and equipment is of

interest to you, for you cannot be sure which of the 20 million interconnecting telephones in this country you may need to reach.

The Bell System provides a constantly improving service at the least cost consistent with financial safety. This means that it pays only reasonable regular dividends and devotes all earnings beyond that to the extension and improvement of the service.

This has been the practice for half a century, with the result that the public has doubled its use of Bell telephones in the last ten years.

The money you pay to your telephone company brings you steadily increasing value.

NUTRITIONAL INSURANCE

EVERYONE knows and understands insurance—life, fire, accident, theft, etc.—NOW, we have reasonable insurance against the very common errors in nutrition!

Vitamin B! BEMAX!

Nutritional workers find that the daily diet of the average individual is lacking in vitamin B. Research finds a definite relation between this deficiency and such common conditions as loss of appetite, malnutrition, retardation of growth and development in the young, derangement of the gastro-intestinal function (including constipation), and general impairment of physical condition and resistance to disease.

BEMAX furnishes the daily diet with abundant vitamin B—in palatable, economical, completely digestible form. It is a delicious supplementary food, rich in vitamin B and other essential elements. It guards against the insidiously harmful effects of vitamin B deficiency. It is nutritional insurance for all ages!

WHAT IS BEMAX?

BEMAX is the embryo of cereals especially selected and biologically standardized for high vitamin B content and thoroughly stabilized against deterioration. You are always assured of its freshness, its vitamin content, and its freedom from rancidity or other forms of toxic deterioration.

How used?

BEMAX is well tolerated over long periods—a necessary requisite in vitamin B therapy. It may be taken alone, or added to milk, other cereals, fruit juices or other foods.

A tablespoonful a day for adults, or a teaspoon or two a day for children furnishes abundant vitamin B.

Mellin's Food

Made from wheat flour, wheat bran, malted barley and bicarbonate of potassium — consisting essentially of maltose, dextrins, proteins and mineral salts

Malnutrition—Marasmus

*Maltose is a
Highly Satisfactory
Carbohydrate
to Increase
Body
Weight*

*Maltose
is the
Predominating
Carbohydrate in
Mellin's
Food*

To improve conditions that may be properly grouped under the above mentioned terms, the first thought of the attending physician is an immediate gain in weight, and the second thought is to so arrange the diet that this initial gain will be sustained and progressive gain be established.

Every few ounces gained means progress not only in the upward swing of the weight curve, but in digestive capacity in thus clearing the way for an increasing intake of food material.

As a starting point to carry out this entirely rational idea, the following formula is suggested:

Mellin's Food	8 level tablespoonfuls
Skimmed Milk	9 fluidounces
Water	15 fluidounces

This mixture furnishes 56.6 grams of carbohydrates in a form readily assimilated and thus quickly available for creating and sustaining heat and energy.

This mixture supplies 15.5 grams of proteins for depleted tissues and new growth, together with 4.3 grams of mineral salts which are necessary in all metabolic processes.

These food elements are to be increased in quantity and in amount of intake as rapidly as continued improvement is shown and ability to take additional nourishment is indicated.

The above modification is one of a series of skimmed milk formulas contained in "Formulas for Infant Feeding" to which reference may be made for complete details. A copy of this book together with samples of Mellin's Food will be sent to physicians upon request.

The World's Worst Bargain

TRADING HEALTH for success is probably one of the most common bad bargains the so-called astute man makes. But relaxation and ambition are seldom on speaking terms. And as long as men can borrow false energy from stimulants, they'll worry about the usurious interest later.

But when it's time to pay up, when they're at the end of their rope, they'll come to you, wondering what they've done to offend nature. And they'll object—perhaps continuing to indulge themselves—if you tell them that caffeine stimulants should go by the board.

Postum, however, offers real help. For Postum is a steaming, flavorsome brew that is cheering to drink, good to drink. It takes the place of drinks containing caffeine with surprising ease. Day after day two and a half million families serve it—and ask for more.

Yet Postum is made only from whole wheat

and bran, roasted to a delectable brown, and slightly sweetened.

Instant Postum made-with-hot-milk has long since proved itself a most valuable addition to the diet in cases of under-nourishment. Patients who dislike plain milk, like it when it is served this way. Postum is a product of General Foods Corporation.

GENERAL FOODS, DEPT. PV-1231
BATTLE CREEK, MICHIGAN

We will be glad to send the physician who addresses us a special gift package containing a full-size package of Instant Postum, together with samples of Grape-Nuts, Post Toasties, Whole Bran, and Post's Bran Flakes. If you live in Canada, address General Foods, Limited, Dept. PV-1231, Cobourg, Ontario.

TRY HIGH VITAMIN B FEEDING WITH

BEMAX

REG. U.S. PAT. OFF.

ENTIRE CEREAL EMBRYO

- In the restricted diet of the invalid
because deficiency of vitamin B lowers resistance to disease and retards recovery.
- In constipation, colitis, and chronic gastro-intestinal disorders
because unsuspected chronic vitamin B deficiency may give rise to these conditions.
- In the diets of infants and children
because an abundant daily supply of vitamin B is necessary for normal growth and development.
- During pregnancy and lactation
because the embryo of cereals not only supplies vitamin B and vitamin G, but other growth-stimulating tissue-building elements as well.
- In the high-caloric diet
because of the effect of vitamin B in maintaining appetite and promoting assimilation and utilization of food.
- In the reducing diet
because these diets must supply in abundance all factors necessary to maintain the health of the tissues during the period of undernutrition.
- In the diabetic diet
because the restricted supply of vitamin-B-containing foods entails a corresponding danger of B deficiency—as shown by the frequency with which constipation on such diets is relieved by vitamin B administration.
- In the normal diet
because an adequate supply of vitamin B is desirable for the maintenance of normal strength and vigor, digestion and bowel function, and the ordinary mixed diet is not rich in this vitamin.

It is the function of BEMAX to restore to the diet elements removed by the degermination and cooking of cereal products. Cereal germ is a rich, natural source of vitamin B.

BEMAX is pleasant, easily digested and well tolerated by infant or invalid; it is a simple natural means of ensuring an adequate supply of vitamin B.

10 CC. DOES THE WORK OF 100

Concentrated Anti-Pneumococcic Serum Squibb, Types I and II,
prepared according to the method described by Dr. Lloyd D. Felton

The use of Concentrated Anti-Pneumococcic Serum Squibb makes possible the administration of ten times as many protective anti-bodies as are contained in an equal quantity of unconcentrated serum.

In addition to the advantage of smaller volume, its concentration eliminates to a large degree the amount of inert protein and lipoids with corresponding reduction of the possibility of serum reaction. Chill-producing substances have also been reduced to a marked degree.

Concentrated Anti-Pneumococcic Serum Squibb, Types I and II, is standardized according to the Felton method, further supplemented by the use of the Hygienic Laboratory test. It is supplied in syringes containing approximately 10,000 units each of Types I and II, measured by the Felton method.

The International Hygiene Exhibition

GEORGE C. DUNHAM, M. D., DR. P. H., F. A. P. H. A.*

Medical Field Service School, Carlisle Barracks, Pa.

THE year 1911 witnessed a unique experiment in health publicity—the first International Hygiene Exhibition in Dresden, Germany. So successful was this exhibit in stimulating interest in health matters that its founders and sponsors conceived the idea that the work so auspiciously begun should be continued by a museum devoted to the instruction of the general public in the conservation of health. As a result, the German Hygiene Museum of Dresden was started in 1912 and, despite the vicissitudes of the World War and the years of reconstruction and rehabilitation which followed, development was continued to completion in 1930. In order that the opening of the new museum might be celebrated in a fitting manner, the second International Hygiene Exhibition was held in Dresden from May to October, 1930.

Dresden has, during the years since the World War, presented a series of annual exhibitions, mostly of an industrial nature. These are not "trade fairs" in the same sense as are many European exhibitions, but are of a cultural nature and designed to depict the progress being made in the industry or profession in question. They are supported financially by the city of Dresden, which is obligated to make good any losses which may be incurred. Grounds with halls are also provided by the city.

The 1930 International Hygiene Exhibition could be roughly divided into two parts, consisting (1) of the exhibits in the halls and on the grounds, and (2) the German Hygiene Museum. The former were temporary and were removed when the exhibition closed. The German Hygiene Museum is a permanent institution and was not

* United States delegate and Army representative at the International Hygiene Exhibition, Dresden, Germany.

View of the Exhibition Grounds

affected by the closing of the exhibition. As the museum is located immediately adjacent to the exhibition grounds there was no physical separation between it and the temporary exhibits on the exhibition grounds proper. Exclusive of the museum, the exhibition grounds comprised some 350,000 square meters of area with about 35,000 square meters of roofed hall space. The museum has 22,000 square meters of useful floor space.

The first and most important purpose of the exhibition was to afford instruction in health matters for the general public by exemplifying and demonstrating methods of conserving and promoting both individual and community health. It was also designed to show the progress that has been and is being made in health practice, not only in Germany but throughout the world.

There were two classes of exhibits—scientific and industrial. The former were supported and extended by the latter and each industrial exhibit was closely connected with and supplemented the scientific exhibits on the particular health feature concerned, the industrial part being subordinated to the scientific aspects. In many cases, however, the industrial portion of an exhibit was in itself of great instructional value.

The scientific exhibits can best be considered grouped into three principal sections. One, the international section, was comprised of exhibits by most of the nations of the world; another consisted of exhibits contributed by various health agencies of Germany, includ-

ing the national government, states, and cities, and societies or associations concerned with health work; the German Hygiene Museum constituted the third.

The international exhibits were housed in a large building known as the "Place of Nations," within which halls were allotted to the various participating nations, among which were France, Great Britain, Austria, Russia, Turkey, Roumania, Switzerland, Czechoslovakia, Jugoslavia, Italy, Holland, Norway, Sweden, Denmark, Danzig Free State, Latvia, Chile, Argentina, Mexico, and Japan. The League of Nations, the Red Cross, and the German Evangelical Missions also had exhibits. The United States was represented only by the exhibits of two commercial firms.

The exhibits varied greatly in character and scope. Some were quite elaborate and extensive, while others consisted only of a few charts and pictures, but each was instructive, and represented a worth while effort. Practically every exhibit showed the incidence of various diseases in the country represented, especially the most prevalent. In most instances some consideration was given the control measures practised. The more extensive exhibits included material dealing with child hygiene, maternal hygiene, industrial sanitation, school sanitation, sports and physical culture, and the control of infectious diseases. Some considered special activities, such as the manufacture

Part of the Place of Nations, showing the hall allotted to the United States

and use of biologicals, the construction of sanatoriums, etc. Others contained special features, such as the health car equipped for epidemiological work which formed a part of the Czechoslovakian exhibit. Models, photographs, placards, drawings and charts were generally utilized.

While the exhibits in the international section generally covered practically all phases of health activities, the greatest emphasis was placed on child hygiene among both the preschool and school children and on industrial hygiene and sanitation. It was quite evident that the nations of the world considered the protection of the child and the industrial worker of paramount importance.

The exhibits of the national government and the states and cities of Germany dealt with practically every phase of preventive medicine, but were primarily intended to depict the present status of health work and the progress being made in the various fields. As the national government as well as each contributing state and city was represented by a separate exhibit, there was some duplication, though each presented distinctive features. A great deal of attention was given to child hygiene, industrial hygiene and sanitation, physical culture and sports, maternal hygiene and community sanitation.

Of the exhibits shown by the German states, those of Saxony and Prussia were the most elaborate. In addition to the usual subjects, the Saxony exhibit considered in some detail the care and education of the blind and crippled, the development of physical culture and sports, the use of labor saving devices, and home sanitation. The Prussian exhibit also presented material pertaining to municipal sanitation and included models of water works, sewage disposal plants, swimming pools, etc. The nature and scope of the work performed by the Robert Koch Institute was shown by means of charts and drawings.

The cities of Bremen and Hamburg contributed excellent exhibits. These contained particularly interesting features pertaining to port sanitation, models of sailors' homes and rooming houses, the control of rats and other rodents, and dock construction. Methods of food control, abattoir construction, and the inspection of food products, were demonstrated by models and pictures.

THE GERMAN HYGIENE MUSEUM

This proved to be the most interesting part of the exhibition, at least for the American visitor. It should be understood that it is not a museum in the ordinary sense but is in reality a teaching institution for giving health instruction to the general public. It has been con-

The German Hygiene Museum

ceived and developed as a central academy of public health. Its sole mission is to bring to the attention of the average person the need for protecting and promoting his health, and to teach the basic principles of health conservation. All exhibits have been arranged with a view to accomplishing this by methods which require the minimum of initiative and effort. In each instance the material has been prepared and arranged with a view to attracting and holding the attention of the casual visitor. Each exhibit is designed to teach a definite and simple lesson and the dominant health feature so emphasized as to force it upon the attention. The exhibits consist of models, apparatus, placards, paintings or drawings. Wherever practicable, moving apparatus, or apparatus with which the observer can perform experiments for himself, is utilized.

Generally, the exhibits on the first floor of the museum pertain principally to anatomy and physiology. The objective is to demonstrate the normal structure and functions of the body and, to a certain extent, the effect which abnormalities or violation of health rules have on the normal structure and functions. Transparent life size models are used to show the location and relations of the bones, blood vessels, nerves, muscles and viscera. Some of these can be lighted to accentuate the part or parts demonstrated. For example, one such model can be lighted so that the cranial, thoracic, abdominal, and pelvic viscera are successively and alternately thrown into bold relief.

Moving models are used, where practicable, to demonstrate the functions of the body, such as models of the joints which can be caused to execute the various movements of which they are capable. An-

*Part of exhibit dealing with hearing. Note instrument used to elicit the various sounds.
(German Hygiene Museum)*

other shows by means of a moving light the pathway of an involuntary reflex motion (patellar reflex). Others are used to demonstrate the mechanism of the heart and its valves, the maintenance of the blood pressure, the movements of the structures of the mouth and throat involved in speech, etc. All or any of these can be operated by the

Exhibit dealing with venereal diseases. (German Hygiene Museum)

visitor and thus serve not only to attract his attention but also to make an impression upon his memory.

Many pictures and placards are used to show the structure and functions of the body.

On the second and third floors of the museum are a number of exhibits, the more important of which are concerned with eugenics, food, care of the mother and child, and the control of the preventable diseases. Models, apparatus, placards, etc., are used in much the same manner as in the exhibits on anatomy and physiology. Skeletons and specimens are used to show the evolution of man from the lower forms of animal life and to demonstrate the different stages of development of the human body.

One exhibit demonstrates the mechanism of childbirth and delivery by life size models and manikins, and the measures which must be taken to prevent infection during childbirth. The hygiene of nursing and methods to protect the health of the breast fed infant and nursing mother are demonstrated by means of models and pictures.

The food or nutritional exhibit is one of the best. All phases of the process of digestion are illustrated by means of models, anatomic specimens, drawings and pictures. The value of each article of food in common use is shown in terms of its constituents. Models of the different products are exhibited which can only with difficulty be differentiated from the real. The amount of food required over a period of time is demonstrated by showing full size models of the actual quantity consumed. Thus, the quantity of potatoes consumed by one person during one year is shown by models of the potatoes. The methods of protecting food and controlling food-borne diseases are shown. The cause, prevention and treatment of the various food deficiency diseases are demonstrated by models and pictures.

There are exhibits which pertain directly to the control of the infectious diseases. While these are less extensive than those discussed above, they are well prepared and presented. That on tuberculosis, for example, consists of models and pictures which graphically demonstrate the avenues of transmission, the methods of prevention and treatment, and prevalence charts for Germany. The exhibit on the pathology, prevention and treatment of cancer is exceptionally good.

The museum also includes well equipped workshops in which the models, apparatus, placards, drawings, and lantern slides used in making up exhibits and in giving instruction are made. These shops employ about 100 persons, including artists, mechanics and other skilled workmen. Much of the product is at present being sold to other museums, schools and institutions engaged in teaching health.

Part of Museum workshops

The German Hygiene Museum is staffed and equipped to give short courses in health subjects to teachers, physicians, students, mothers, and various other classes of the general public. The permanent teaching staff consists of about 6 instructors, which is supplemented by specialists from the outside who give instruction on specific subjects. The instruction consists of lectures and demonstrations. The equipment includes well appointed lecture rooms and the models and other exhibits of the museum. Lantern slides are extensively used. The teaching facilities are extended to other communities in Germany by traveling exhibits and teaching personnel.

Nearly all parts of Germany have been reached by the traveling exhibitions. A specially constructed motor truck is used to transport the exhibits and personnel to isolated villages and rural sections. It carries a large tent to house the exhibition and is equipped with an electric lighting unit.

The German Hygiene Museum has shown its exhibits or held organized exhibitions in a number of foreign countries, notably Austria, Switzerland, Hungary, and Czechoslovakia. Exhibits have also been sold to foreign museums.

The International Hygiene Exhibition included certain miscellane-

ous exhibits more or less directly concerned with health conservation. Among these was a hospital exhibit, a model farm, and a model home. The first was housed in a separate building and was designed to demonstrate the functions of a hospital and to show the value of the hospital in the maintenance of health. All the various parts and sections of a modern hospital were shown: clinics, operating rooms, wards, laboratories, etc. Much of the equipment was arranged just as it would be in a functioning institution.

The model farm was installed in an adjacent park. It included a farm house and other farm buildings and was stocked with all of the usual animals, showing the approved arrangement of farm facilities and methods of caring for live stock. It included a building in which models, pictures and specimens were shown depicting the cause, transmission, control and treatment of the diseases of animals.

The model homes exhibit consisted of a number of buildings of different sizes, each of which was furnished and equipped as a home, demonstrating the approved methods of construction, of installing plumbing, of lighting and ventilating.

Despite unfavorable weather, about one and one-half million persons were admitted between the opening date and August 1. The general admission fee was 2 marks (48 cents).

The exhibition as a whole did not include anything that was original from a scientific viewpoint. It did, however, offer the trained health worker much food for thought in the field of health publicity. It was everywhere evident that a great deal of study and labor had been devoted to attracting and holding the attention of the visitor and thus developing the salient health lesson of each exhibit or group of exhibits. The museum is, moreover, of special interest to American health workers from the viewpoint of health

Transparent man showing the location of the viscera. This model is automatically lighted to show the location and relations of the various organs. (German Hygiene Museum)

publicity. The character of the museum exhibits and their arrangement indicate that a thorough study had been made of the psychology of the average museum visitor. Every exhibit has been prepared and arranged with all the thoroughness and ingenuity so characteristic of the German workers. Wherever practicable, advantage was taken of the tendency of the average person to visit a museum for the purpose of being entertained rather than instructed. The entire museum is in fact a valuable demonstration of methods of health publicity, and is well worthy of study by any health officer. Certainly, anyone engaged in public health work who visits Germany should visit the German Hygiene Museum.

Effect of Methanol Anti-Freeze on Health

SURGEON GENERAL H. S. CUMMING of the U. S. Public Health Service, when asked regarding the statement issued December 6 by the Bureau of Mines on the effect of methanol anti-freeze on health, stated that the Service had kept in touch with the observations being made by the Bureau of Mines on the subject, and that he felt there was need for the immediate release of information which would protect the general public. It appeared from the study so far that there was much more danger from exhaust gas (carbon-monoxide) than could possibly come from methanol when used strictly as an anti-freeze liquid in automobiles.

The greatest danger is that some one might drink methanol, especially in view of its being used in place of ordinary denatured alcohol as an anti-freeze, and in view of its other name, methyl alcohol. Methanol when taken internally is more certainly poisonous and more highly fatal than any denatured alcohol. According to press accounts, such poisoning has recently occurred in Pennsylvania.

Another danger is in the use of methanol in shellacs which might be applied over considerable surfaces without adequate ventilation. The presence of the coloring matter as recommended by the Bureau of Mines, and the addition of 23 per cent water as at present dispensed, guard anti-freeze methanol against such dangerous use.

A complete study is advisable as to how far methanol can be used safely in other ways; in the meantime, the Surgeon General recommends that methanol be used by the general public as an anti-freeze only, and that the precautions advised by the Bureau of Mines be strictly observed.—*Health News*, G-52-A, U. S. P. H. S.

Comparison of the Dominick-Lauter Test for *B. coli* in Water with that of "Standard Methods"

Final Report

HAROLD W. LEAHY, J. W. FREEMAN, AND CHRIS P. KATSAMPES

Rochester Health Bureau Laboratories, Department of Bacteriology, School of Medicine and Dentistry, University of Rochester, Rochester, N. Y.

THOSE who have used standard lactose broth as a presumptive test medium for detecting *B. coli* in water know that a large number of positive tests are obtained from which members of the colon group cannot be isolated. Many workers have shown that these spurious presumptive tests, caused by either spore-forming organisms, symbiotic combinations, synergistic combinations, etc., introduce an error approaching 100 per cent during certain periods of the year. Errors of this sort greatly depreciate the value of standard lactose broth when used for the examination of waters, for it becomes necessary to make a confirmatory test that requires from 48 to 96 hours longer before a definite result can be reported. This procedure may take as long as 6 days for completion, which is too long for the test to be of immediate value to the water control analyst or to the sanitarian.

It would seem advisable, therefore, that there be found a shorter method of water analysis giving definite and accurate results within 24 to 48 hours. The procedure adopted should give as reliable results as the Standard Methods completely confirmed test, at the same time being as simple as the standard lactose broth presumptive test. It was pointed out in a preliminary report¹ that these conditions are satisfied by the new methylene blue bromocresol purple medium of Dominick and Lauter.² In this preliminary study, a comparison of the new medium with standard lactose broth was made on 300 samples of water from 91 different sources; the results showed that the per cent confirmation for the new medium was much higher than for standard lactose broth. This comparison has been continued until now 1,116 samples from 358 different sources have been examined. The results obtained bear out the conclusions of the preliminary report and conclusively show that this new medium is far superior to standard lactose broth for the detection of *B. coli* in water.

Procedure for the Comparison—The method of comparison for most water samples consisted in inoculating three 10 c.c., three 1 c.c., and three 0.1 c.c. quantities of suspected water into a corresponding number of tubes of the standard lactose broth and the Dominick-Lauter medium. In the case of waters known to be of good sanitary quality, five 10 c.c. and three 1 c.c. tubes were used. In the case of samples known to be highly polluted, greater dilutions were made in order to insure that the last dilution be negative. The tubes were then incubated from 24 to 48 hours, and as soon as 10 per cent or more of gas was formed in any of the tubes *all* gas positive tubes, regardless of dilution, were carried through the complete confirmatory test as outlined in Standard Methods.

Eosine-methylene-blue agar was used for the isolation of *B. coli*; two typical colonies from each plate being transferred to agar slants and lactose broth tubes. The formation of gas in the lactose broth tubes and the demonstration of Gram negative non-spore-forming bacilli in the agar cultures were considered as positive confirmatory tests. If such an organism failed to materialize the tests were considered negative for *B. coli*.

Preparation of Media—The standard lactose broth, eosin-methylene-blue agar and plain agar slants were prepared according to Standard Methods.²

The new medium was prepared as directed by Dominick and Lauter² with the exception of slight modifications recommended in a communication from J. F. Dominick. The corrected formula as used in this work is as follows:

Lactose	10	grams
" Bacto " peptone	10	grams
" Bacto " beef extract	5	grams
K ₂ HPO ₄ ·3H ₂ O	14.3	grams
KH ₂ PO ₄	2.0	grams

These substances were dissolved in 2 liters of distilled water at a moderate temperature (50–60° C.) and when dissolved there were added:

1.6 per cent alcoholic solution of bromocresol purple	4 c.c.
1.0 per cent aqueous solution of erythrosine	1 c.c.
1.0 per cent aqueous solution of methylene blue	20 c.c.

For the 10 c.c. inoculation of suspected water the above medium was tubed in 15 c.c. quantities, but for the smaller amounts 600 c.c. of distilled water were added to a 1 liter batch of this stock and this was tubed in 15 c.c. quantities. For pure culture work 666 c.c. of distilled water should be added to 1 liter of the stock media. The pH of the medium was determined electrometrically with a quinhydrone electrode and found to be pH 7.2.

TABLE I

TYPICAL REACTION OF *B. coli* IN THE DOMINICK-LAUTER MEDIUM

<i>Bact. coli</i> Strain no.		12 hours	18 hours	24 hours	48 hours
11	Color	Blue	Yellow-orange	Yellow-orange	Yellow-orange
	% gas	0%	1%	50%	50%
12	Color	Sl. yellow	Yellow	Yellow	Yellow-orange
	% gas	0%	2%	50%	50%
13	Color	Blue	Yellow	Yellow	Yellow-orange
	% gas	0%	0%	50%	50%
14	Color	Sl. yellow	Yellow-orange	Yellow-orange	Orange-red
	% gas	0%	2%	50%	50%

In order to become familiar with the reaction of the new medium, a few tubes were inoculated with known strains of *B. coli*.

In Table I are shown the results of these preliminary inoculations with four stock strains of this organism. The results of this experiment showed that there was a color change preceding gas formation which in some cases occurred as early as 12 hours after inoculation. This yellow to orange-red color and the large amount of gas formed is the typical reaction of the new medium to the growth of *B. coli*. This large amount of gas produced in the new medium might indicate the ability of *B. coli* to utilize the lactose in the new medium to a greater degree than in standard lactose broth.

The comparisons of Dominick and Lauter were apparently limited to four types of water all from the same source. Since it is quite well known that different sources of water vary as to their content of gas forming organisms or combination of organisms not belonging to the colon group, it seemed advisable to make the comparison on as many different sources as possible. The samples received by the Rochester Health Bureau Laboratories for examination suited this purpose admirably. Besides these a few additional samples were taken during a sewage pollution survey at the mouth of the Genesee River as it enters Lake Ontario, and a few others gathered from wells, springs, and creeks in the surrounding country. In this way the total of 1,116 samples from 358 different sources was obtained.

On comparison it was found that a much larger number of gas positive tubes was formed in standard lactose broth than in the new medium, but on confirming *all* tubes it was evident that a much higher per cent of confirmation was obtained for the new medium than for standard lactose broth. From the results in Table II it will be seen that of the 2,436 tubes of standard lactose broth showing gas, only 1,634 (67.1 per cent) were confirmed, while of the 1,475 tubes of

possibility of obtaining a negative result from a positive sample when only *one* tube is chosen for confirmation. In the case of the new Dominick-Lauter test, however, gas formation is in itself a completed test in over 98 per cent of the cases where only one tube shows gas, and where two or more tubes show gas, it was found to be complete in 100 per cent of cases.

FIGURE I

FIGURE II

The samples that showed agreement and disagreement are summarized in Table II. The final results obtained by both mediums showed agreement in 95.3 per cent of samples, whereas 4.7 per cent (53 samples) gave contradictory results. Examination of these 53 samples discloses the fact that 29 were Dominick-Lauter positive and Standard Methods negative while 24 were Standard Methods positive and Dominick-Lauter negative. It would seem to us that these variations could be explained by a combination of the law of probability with the very low colon index of the samples showing disagreement. Analysis of the data obtained from the records of these samples shows that in most cases only one or two 10 c.c. tubes showed gas, and in no case did more than one of the 1 c.c. tubes show gas; a fact which seems to support this view.

Another point of importance concerning the per cent confirmation is the comparison of the confirmation for the presumptive tubes showing gas at 24 and 48 hours. This correlation is shown in Table III and Figure I. The per cent confirmation for the standard lactose tubes showing gas at 24 hours was found to be much higher than the 48 hour gas positive standard lactose tubes, but the per cent confirmation for the 24 hour and 48 hour gas positive Dominick-Lauter tubes was approximately the same. In each case with the Dominick-Lauter medium the per cent confirmation was always between 95 and 100 per cent. This would indicate that as the length of time increases before

TABLE III

COMPARISON OF THE PRESUMPTIVE TUBES SHOWING 24 AND 48 HOUR GAS

	Standard Methods						Dominick-Lauter					
	10 c.c.	1 c.c.	0.1 c.c.	$\frac{1}{100}$ c.c.	$\frac{1}{1,000}$ c.c.	$\frac{1}{10,000}$ c.c.	10 c.c.	1 c.c.	0.1 c.c.	$\frac{1}{100}$ c.c.	$\frac{1}{1,000}$ c.c.	$\frac{1}{10,000}$ c.c.
Tubes pos. in 24 hours	470	480	296	57	16	7	472	283	127	25	13	6
Tubes pos. in 48 hours	680	290	130	7	3	0	286	169	79	12	3	0
Total tubes gas pos.	1,150	770	426	64	19	7	758	452	206	37	16	6
No. of 24 hour tubes confirmed	387	416	266	49	15	7	472	280	127	24	13	6
No. of 48 hour tubes confirmed	301	133	51	4	2	0	272	160	78	12	3	0
Total tubes confirmed	688	549	320	53	17	7	744	440	205	36	16	6
Per cent of 24 hour tubes confirmed	82.7	86.6	83.1	92.5	88.2	100	100	99.0	100	96.0	100	100
Per cent of 48 hour tubes confirmed	44.3	45.8	41.5	57.2	67.6	100	91.7	91.6	98.7	100	100	100
Per cent of all tubes confirmed	59.8	71.3	75.1	82.8	89.5	100	98.2	97.3	99.5	97.3	100	100
Per cent of all 24 hour tubes confirmed						89.9	99.6					
Per cent of all 48 hour tubes confirmed						39.9	95.8					

the production of gas in standard lactose broth, the per cent confirmation decreases. This fact supported by others' necessitates the confirmation of *all* tubes of standard lactose broth showing gas in 48 hours. The per cent confirmation for the new medium, however, remains so high in both instances that it would seem unnecessary to confirm either the 24 or 48 hour gas formations; a point which favors its adoption for both rapid and accurate detection of *B. coli* in water.

In calculating the per cent confirmations for the various dilutions it was immediately noticed that the per cent confirmation increased with the dilution in the case of standard lactose broth, but remained approximately the same in the Dominick-Lauter medium. This relationship, illustrated in Table II and Figure II, may be considered an index determining the relationship of the per cent confirmation to the amount of pollution existing in the suspected waters. The samples showing gas in the high dilutions (10^{-4}) may be considered as polluted water and those showing gas in the low dilutions (10^1) as question-

able waters. When this was correlated on coördinate paper, as shown in Figure II, it was found that the per cent confirmation for standard lactose broth was very low for the questionable waters, increasing as the pollution increased until it approximated 100 per cent. In the case of the new medium the per cent confirmation was always between 95 and 100 per cent regardless of dilution,

FIGURE III

showing the superiority of the new medium for detecting *B. coli* in waters of questionable sanitary quality. This fact seems to be true for both the 24 and 48 hour gas formations as illustrated in Figure I.

If the number of standard lactose tubes from which *B. coli* was isolated and the number of Dominick-Lauter tubes that showed gas be plotted as ordinates, the various dilutions being plotted as the abscissa, the graph obtained should show at once whether or not there are any large deviations in the colon index obtained by either method. It was found (Figure III) that the number of positive results obtained from the various dilutions was approximately of the same magnitude for either method; the maximum deviations being ± 57 or 3.6 per cent from the mean of the total number of tubes considered to be positive. This correlation again brings out how clearly the results of the Dominick-Lauter test compare with the results of the completely confirmed test of Standard Methods.

SUMMARY AND CONCLUSIONS

1. Eleven hundred and sixteen samples of water from 358 different sources have been tested according to the procedure of *Standard Methods of Water Analysis*² and compared with the new methylene blue bromocresol purple medium of Dominick and Lauter.³

2. The per cent confirmation for the total number of tubes showing gas and the total number of samples showing gas was much higher in both cases for the new medium than for standard lactose broth.

3. The per cent confirmation for the standard lactose tubes showing gas in 24 hours was higher than the per cent confirmation for the standard lactose broth tubes showing gas in 48 hours, but the per cent confirmation with the Dominick-Lauter tubes showing gas in 24 hours and 48 hours was approximately the same in each case.

4. The per cent confirmation for standard lactose broth increased as the amount of pollution in the water being tested increased, whereas the per cent confirmation for the new medium remained approximately the same.

5. Of the total *samples* showing a positive presumptive test 100 per cent were confirmed for the new medium whereas only 68.7 per cent were confirmed for standard lactose broth.

6. The new Dominick-Lauter medium was found to be far superior to standard lactose broth for the detection of *B. coli* in water.

Chronic Lead Poisoning in Infancy and Early Childhood

THE Metropolitan Life Insurance Company, as a result of a recent inquiry among prominent pediatricists, calls attention to the large number of cases of lead poisoning occurring among infants and children. The brief note points out that a Boston physician reports 50 cases of lead poisoning among children at a Boston hospital during the past 6 years. In these cases the diagnosis was proved beyond doubt, the source of lead being the paint on cribs, woodwork and toys.

It seems obvious that the simple precaution of using zinc paints in these cases should be resorted to. Lead poisoning due to the use of nipple shields and of lead ointments on the breasts of mothers was also considered a source of poisoning by the physicians interviewed.—*Stat. Bull.*, Metropolitan Life Insurance Company, 11, 10: 4 (Oct.), 1930. L. G.

The Research Laboratory and the Public Health Work*

ARISTIDES AGRAMONTE, M. D., Sc. D., LL. D.

Ex-Secretary of Public Health and Charities, Republic of Cuba, and Professor of Bacteriology, University of Havana, Havana, Cuba

EVERY human endeavor, no matter how dry, all-absorbing or painstaking, carries with it a breath of sentiment as an inseparable complement of all that is great, good, true, and beautiful. Thus, in a gathering of men who meet primarily to discuss our present knowledge and the manner of solving serious and abstruse problems that require intense labor and thought concentration, there is this sentimental note, this delightful exponent of fraternal good will and professional solidarity, both uniting us in a common aspiration: to rise and go forward in our purpose to preserve the good health and to prolong the life-term of our fellowmen.

The progress obtained in the methods of safeguarding the public health, slow in its evolution during the early days, while human conscience and human reason remained apparently divorced one from the other, has attained gigantic proportions since the end of the 19th century. Free criticism and experimental methods applied to scientific investigation tend to light the way toward future and more exalted accomplishments. Hence, the work of the sanitarians cannot but receive the approval and praise of the population, and their meetings be a stimulus that draws the sympathies of all good-minded citizens, but a greater human sympathy must be stirred up by an assembly of this kind; to the scientific student, willing to devote his lifetime to the quest for truth that may add to the health and happiness of his fellows, it offers a reward that cannot be measured in money values, one that can only be found in the consciousness of the highest duty well done. I am proud to be with you tonight and, in appearance at least, to have taken a place within your ranks, for no other branch of our professional activities affords a greater measure of satisfaction to those who follow it; the priceless reward that comes to him who has unveiled one of

* Delivered at the Third General Session of the American Public Health Association at the Fifty-ninth Annual Meeting at Fort Worth, Tex., October 30, 1930:

nature's secrets and, by presenting it to his fellowmen, contributed thus to their happier or more contented lives.

In justice to this, I believe, every measure that this Association may have recommended is sure to receive favorable consideration on the part of the state and the federal governments and the health authorities connected with them, inasmuch as their duty is not only at present and materially to preserve the human body of the inhabitants, but also to prepare to defend it against conditions that finally tend to weaken it morally and intellectually, for—when studied from another point of view—hygiene, after all, constitutes an important chapter in moral philosophy. The physiologist Flourens has remarked that we do not die as a result of our habits, our passions, or our miseries, but that we kill ourselves with them. Recognizing this fact, public hygiene, or applied physiology, as it is called by Claude Bernard, has developed precisely into the guide to good habits, the guardian of our lives, which should prevent its shortening, its waste or its disruption.

It was not my intention to take up your time expatiating upon the wonderful and profitable worth of sanitary activities in our civilized communities, but more to call attention to, and demand a higher appreciation on our part of, the work of those men who labor unostentatiously, often almost unnoticed or unknown, in the research laboratories, hardly ever rewarded for the toil of months or years, sometimes the best of their lives, and without whose aid the ideas we have drawn of the greatest sanitary problems would still be in their infancy.

As the years pile on to constitute old age, one is prone to devote much time to reminiscences, and from such one is apt to fall into comparisons, notwithstanding the fact that, to the losing side at least, comparisons are always odious.

But life at its best, if it is to be enjoyed at all or well directed, must be made up of a series of comparisons, or computations of relative values, and it is only by establishing a proportional analogy between things that we come to appreciate clearly what is now better than before, or what has not improved, or what has even grown worse, in the years that serve as a criterion.

"Lest we forget," it is well to look back now and then and contemplate, from our heights of well-being and success, the extensive vistas of the recent past, lying at our feet, here and there seared, or wilted, or killed by the passage of time, while other patches within our view remain verdant, quite fresh and fruitful in their sterling worth.

The sciences that are involved in the practice of public health administration have certainly not been at a standstill; the subject of its colossal development as a whole, within the first quarter of this cen-

ture, is a source of the greatest admiration on the part of all public spirited citizens and the merest reference to some of its outstanding achievements cannot but fill our hearts with satisfaction; they broaden our horizons in the sphere of optimism for the greater preservation of life and health and induce us to hope for the total and final eradication of certain diseases that so forcibly strike mankind, that weaken it or despoil it sometimes in childhood, at others, in adult life.

The control of disease, in a general way, may be said to have been obtained only with regard to the infectious, or contagious maladies; all the others, not to mention the exceptions that prove the rule, have practically remained unaffected by any measures at our command; and in some cases, indeed, certain diseases seem to be on the increase. A general wave of what we might call "life extension practices"—which include the periodic medical examination with the resultant advice tending to correct deficiencies in diet or erroneous methods of life—that has spread into the homes through publicity campaigns of life insurance companies, backed by the support of the family physician, has led to a marked diminution in the incidence of those diseased conditions arising from disturbances of metabolism, degenerative processes, faulty renal, circulatory or glandular function, etc. These, although they do not play a very significant rôle in the demographic records, are frequently secondary or predisposing causes in the case of the infectious diseases. On the other hand, the great interest that has arisen in the direction of mental hygiene, as shown by the recent world congress held in Washington, must inevitably cause great advancement in the prevention of psychiatric conditions, a subject never heretofore considered with the attention and care that it certainly deserves. The movement is only 22 years old; its progressive development until the constitution of an International Committee promises well for the future of this long neglected branch of public hygiene that more than other better known allied sciences strikes directly at the prevention of extreme poverty, of immorality, vice, and crime, all these leading in one way or another to disease.

It is however with the infectious diseases, the most flagrant and widely disseminated, that we have been able to cope most successfully, and in all such cases—when we come to study their early history and the gradual evolution of our knowledge regarding them—we must admit that the research laboratory, by the discovery of facts relating to their origin and manner of propagation, established the basic principles that have served for our effective health campaigns. In some instances, the laboratory workers only brought forth the etiologic factors connected with the disease, but more often they went further and,

through wise experimentation with animals and by the discovery of biologic reactions, arrived at facts which made for early diagnosis, for specific vaccination, for immunization—the three mainstays of all extensive sanitary activities. The research laboratory has been the keystone that held together all the other contributing elements that have gone into the building of the magnificent temple erected to public health. But the laboratory has rendered valuable aid in other fields of the public health administration. Inasmuch as a state of health is not only freedom from disease, but also the attainment of normal development of brawn and brain, in the research laboratory are also carried out the investigations of food stuffs as to their health giving and vitality producing contents, not to mention their purity from a chemical or bacteriologic standpoint.

Just as symptomatology of disease and the science of therapeutics can only develop through clinical observation by the bedside, just so the control and suppression of disease can only be reached through, and is always based upon, some previous laboratory investigation.

The *fulcrum* that has served to move in a progressive direction the practice of public health administration may be represented by the intelligence of the people in combination with the campaigns of popular education in such matters, but the *lever* that has steadily promoted its advancement and raised it, I am glad to say, particularly in this country, to the level of the highest standard and the most far-reaching and beneficent pursuit, has been the work of research laboratories.

Every year, the A. P. H. A. through its special committees is bound to renew or modify methods or criterions mainly in relation to laboratory activities, without which a thorough application of modern processes in public hygiene would be difficult if not absolutely impossible.

I know we cannot boast of our success with cancer, or insanity, or with some of the endocrine diseases, but think what has been accomplished in the last 25 years and be satisfied and proud, if you like, respecting intestinal infection, tuberculosis, diphtheria, cholera, typhus, typhoid and yellow fever, and notice that all these have had the laboratories constantly at work in the solving of their etiologic problems.

Not wishing to make this modest address too wearisome or long-drawn, allow me to mention only one or two examples in which this decided help of the research laboratories has led to the remarkable success of the sanitary campaigns, based upon their findings. I will not, even cursorily, examine the problems of tuberculosis, plague, or cholera, where a decided impression has been made by the application of intelligent sanitary measures based upon their etiology and epidemiology, but let me draw your attention to diphtheria. I believe

that this is one of those diseases that will ultimately be left out of our mortality statistics.

Many of you must remember when the means at our command were practically unavailing in the treatment of this malady, how entirely beyond all efforts was the manner of its prevention. Barely 35 year ago—the scene is still vivid in my memory today—one of the most eminent pediatricians of all time, who had been called in consultation, Dr. Abraham Jacobi, and I stood in impotent dismay before the bed of a 5-year old child whose life had been prolonged the day before by means of an O'Dwyer laryngeal tube, and watched it ebb away now as a result of diphtheritic toxemia. The parents could have well paid half a million dollars to save their boy's life, and would willingly have done so, had it been possible. This was only a year before von Behring discovered antitoxin and only 2 before Park had it ready in New York. We see no such thing today; it would be deemed criminal negligence to allow such an instance to occur. Yet, if antitoxin, that excellent weapon in the hands of the clinician, has been the means of saving life, and, within certain limitations, preventing the disease from widely spreading, it loses much of its importance when compared with the later possible achievements in the field of prophylaxis. When Dr. Schick developed the test that allows the exclusion of immune children from any fear of infection, he only laid the foundation stone upon which you shall build one of the grandest monuments to preventive medicine, inasmuch as by immunizing the susceptible child, the fertile soil will be totally suppressed and, as the earlier physicians would express it, the disease for lack of *pabulum* will naturally die out.

The marvelous results of the procedure are self evident in numerous states. I am not going to fall into the trap of quoting statistics at this time, for I am sure of an unanimous opinion from this audience, that the toxin-antitoxin or the anatoxin immunization has been one of the most outstanding triumphs of man over disease.

Up to the last days of the 19th century we were absolutely in the dark as to how the malarial plasmodium got into the human system, although for 20 years we had been looking at it in the blood of our patients through the microscope. Just as so many other great truths have evolved out of the laboratory this came as a result of laborious research undertaken by Ross, and primarily by analogy with the malaria of birds. Subsequently the experiments of Low, Grassi, and their assistants in the Roman Campagna, and the transportation of infected mosquitoes to London where young Manson voluntarily contracted the disease through their bites, placed in the hands of sani-

tarians what seemed to be, at the time, the logical means for its control if not its eradication. The problem, however, has proved to be a many-sided one and, in truth, though many well directed campaigns have been carried out all over the world, sanitarians cannot on the whole be as satisfied with the results as with those obtained in other fields of their prophylactic efforts. Notwithstanding this, the knowledge of the mosquito transmission in this disease has enabled the people to reach marked improvement in health conditions in territories where life, until then, had been almost impossible; it has allowed the reclaiming of vast areas to the purposes of agriculture, or mining, and thus to the wealth of the countries involved.

The mosquito as a close neighbor is a nuisance, of course, but the consensus of opinion is gradually turning, in its search for a desideratum, more toward the malarial patient than the mosquito and, without losing sight of the latter, to treat the former, prevent the formation and, if already formed, eliminate the gametes from his blood and thus render the insects inoffensive, though bothersome.

You are all perfectly acquainted with such work, and the records show how a continuation of Gorgas's methods in Panama, with slight modifications, has kept the Canal Zone quite safe and habitable. In the Cuban and Central American plantations of the United Fruit Company, a business enterprise with a wonderfully well organized and equipped medical department, the latter has been enabled to promote greater sanitary improvements in those countries than their political governments could have done; the reduction in the morbidity and mortality of malaria has been nothing short of miraculous. You are no doubt acquainted also with the work of the National Malaria Committee in this country, its wide scope and its remarkable accomplishments in the line of malarial control and prevention, particularly in the southern states. In spite of all this, I fear that, for a long time, we shall see no such spectacular phenomenon in the way of its repression as we have had the privilege to witness in other of the infectious diseases. Of course, you are not so much concerned about it as we are in the tropics, but the North is the guiding star and we look to you, gentlemen, to carry the standard in this connection as triumphantly as you have done heretofore.

The one disease, to mention only one more, that has been as theatrical in its development as it has in its almost complete disappearance, as though at the waving of a magic wand, thanks to capable public health administration, has been yellow fever.

The idea of its connection with mosquitoes, suggested by some (Rush, Nott, McDowell) and directly pointed out by others (Beau-

perthuy, Finlay), was finally made a reality by the researches of the U. S. Army Board in 1901.

The discoveries of this Board, clearly demonstrating the manner in which man to man infection (Finlay's theory) took place, put into the hands of Gorgas and his followers the principles upon which to establish their campaigns.

It was no easy matter, that investigation that demanded human beings as subjects for the experiments, although within a period of 6 months it was completed and, besides the constant, almost incessant work, there were stirring moments of depression, of disappointment, that the investigators suffered, requiring a large amount of optimistic enthusiasm in the face of discouraging circumstances. Two of them developed yellow fever, one of them, Jesse W. Lazear, losing his life thereby. The sacrifice thus offered seemed to have appeased the furies of the dreaded scourge and, as you know, with the knowledge obtained, Gorgas instituted measures that extirpated the fever from Cuba and later made possible the building of the Panama Canal. Very soon after, other localities fell into line—Laredo, New Orleans, Vera Cruz, Rio Janeiro, Guayaquil. Today it can be found nowhere but in semi-civilized communities, the indigenous element constituting an almost insurmountable barrier to its complete eradication.

Like plague, typhus, psittacosis, diphtheria, and cerebrospinal meningitis, yellow fever has taken heavy toll of human life from among those engaged in its investigation: the names of Lazear, Cross, Stokes, Young and Noguchi have thus become consecrated and immortal.

Such epic histories cannot be often written into the annals of medicine, but they serve to point directly at what may be expected from the concerted action of specially trained men, instigated by noble motives, the work being carried out with perseverance and courage.

My object in selecting this fragmentary subject has been, not to shed wisdom upon matters best known to most of you, much less to entertain you with tiresome, because too oft repeated, references to noble work and achievement, but more to promote interest in some historical points of our vocation; not as a simple narrative, or a haphazard story, but as reminiscent of the evolution of great constructive ideas which took life in minds of the pioneer stamp of man.

All of you, I know, *have done things*; many of you have the good fortune to be still engaged in that all-absorbing work that deals with the preservation of your community's health; you are experiencing gratification such as comes only to the chosen ones. I salute you all and join hands with the few who, like myself, are eagerly watching, standing by, with a heart full of thanks.

Control of Measles by Honorary Quarantine

L. W. BRIDGMAN

Publicity Editor, Wisconsin State Board of Health, Madison, Wis.

THE history of many outbreaks of disease shows them to simulate a fire, trivial at its origin but becoming more menacing and dangerous as new fuel is offered. By limiting the material upon which to feed, a fire may quickly be curbed; it is by similar disciplinary action that the highly communicable disease of childhood, measles, may peremptorily be controlled. Deny it more human fuel and measles will die a natural death.

This analogy was given convincing proof in the experience of the Village of Shorewood, Wis., an attractive suburb of 13,000 people adjacent to the City of Milwaukee, during the winter of 1929. In this municipality, where home-owning is a religion and community spirit has many commendable manifestations, the local Health Department proved that with full public coöperation an epidemic of measles can be brought speedily into subjection. Needed for the test in Shorewood was a community "healthmindedness," which was never lacking, and which found expression in popular coöperation with officials that remained at 100 per cent.

When measles spotted Shorewood's morbidity records early in January, 1929, and gained weekly accessions, Walter G. Darling, M.D., Health Commissioner, proposed to his Health Board an arbitrary procedure not founded in precedent, and received its support. Upon the community public health nurse, Irene H. Hansen, R.N., fell the responsibility for tracing the hundreds of contacts and imparting special instructions.

Shorewood's policy did not depend alone upon school inspection, since this fell short of controlling sufficiently the children exposed. The principle was followed of isolating and placarding the homes of all "contacts" (exposed persons not having had measles), and treating them as though they were actual cases. This was considered in the light of an "honorary quarantine."

School inspection is of much value in detecting cases and eliminating many contacts. But it was Shorewood's experience that some children showing no symptoms at the morning inspection, say 9 A.M.,

would by afternoon show beginning symptoms of measles, thus proving that the symptoms may develop between inspections on the same day. It was manifest that measles is infectious before any marked signs of the disease appear. This was believed to be sufficient reason for isolating all exposed children without waiting for symptoms to develop. Taking advantage of a closely knit community organization, the Health Department elected to enlist the existing public health morale among the citizens in the trial of this plan.

The "honorary quarantine" implied exclusion from school and other public places, even from the streets and playgrounds, not only of children who showed symptoms, but also well children who showed no visible evidences of measles, and against whom there was only the proof that they had associated with actual cases. Those exhibiting symptoms were subject to the usual placarding, and in the case of the contacts, without symptoms, the Health Department asked that an isolation of 10 days be rigidly enforced, to begin 7 days after known exposure. This was done, of course, to allow for variations in incubation, and time proved its wisdom beyond dispute.

A suspect card, about 3" by 5", authorized by the Health Board, was posted on every home harboring exposed children:

MEASLES CONTACT WITHIN

All persons are notified of a Measles Contact in this home, and on account of its communicable character before the actual onset of measles are warned against visiting or coming in contact with this case.

Measles contacts are prohibited from leaving the premises or coming in contact in any way with the general public.

All persons are forbidden to remove, obscure or mutilate this card or to interfere in any way with these restrictions, under penalty of a fine or imprisonment as provided in section 143.11 of the statutes.

By Order of the Board of Health, Village of Shorewood.

At this time the surrounding communities were experiencing measles epidemics, necessitating extreme care as to companionship not only in Shorewood but in other communities. In special bulletins Dr. Darling strongly urged that children who had not had measles be kept from all gatherings of whatever nature during the subsequent 2 weeks, and that visiting children who had never had measles be tactfully excluded from the placarded homes. It was emphasized that efforts would be of no avail unless parents exercised unusual vigilance with regard to the contacts which these children were allowed to make *outside of school*. This also applied, of course, to preschool children. The local baby clinic was discontinued for 2 weeks.

The epidemic's beginnings were of an explosive character. Twelve cases of measles were reported on January 7. All were traced di-

rectly to a church party held on December 24. Obviously, it was concluded, all had been exposed by a certain child at the church gathering. Through diligent tracing of contacts by the nurse, this case was discovered, the only one unreported during the epidemic.

On January 21, the list was augmented by 65 new cases, 20 of which were from already quarantined homes, leaving 45 new exposures, who were contacts of only 7 children out of the original 12 cases. The remaining 5 had no contacts and terminated with the family. By this time it was plain that an epidemic loomed, and efforts were made to exclude all exposed well children from schools and public places.

By January 24, the nurse's inquiries had revealed 200 known contacts who had never had measles. The entire group was excluded from school for 2 weeks. This was later reduced to 10 days, to begin 1 week after exposure, as a safer and more practical rule. As new exposures developed their contacts were excluded and a suspect card posted on their homes.

By January 31, 44 more cases had been listed, and on February 4, the number was increased by 71, all springing from the original 200 contacts who had been excluded from school and now had suspect cards on their doors.

By this time the fuel for the outbreak had been cut off and further infection prevented. From February 4 through the month the new cases fell off with regularity, the week of February 11 showing 21 new cases, February 18 the same number, and February 25 8 cases. In exactly 1 month from the exclusion of contacts (January 24 to February 25), the epidemic had completely subsided. The peak was reached on February 4 with 115 cases. In all, 250 cases were recorded. No complications or deaths occurred and, in accordance with the advice published by Dr. Darling, practically every case had the attention of the family physician. The epidemic's early termination, without fatalities, can be ascribed to the systematic following up of the contacts.

A child broke out with measles 3 days after attending a birthday party. Her association with playmates there resulted in 6 others developing measles. Their discovery was prompt and their exclusion saved the possible exposure of four school rooms and the infection of a different community. Again was the value of diligent tracing of contacts proved.

In Shorewood there are four school buildings, a high school, a parochial school, and two grade schools. Measles was a disturbing factor in three of these. It is interesting to note that the fourth, a parochial school with 439 pupils, situated across the street from the

Atwater school where there were many cases among the 798 enrolled, was untouched by the epidemic, escaping without a single exposure. This school had been prepared to handle such a situation and had given complete coöperation with the Health Department. The pupils followed all instructions to the letter. School was called and dismissed 15 minutes earlier than usual to avoid street contact, and unusual care was taken to prevent contact with any children not attending their school during the course of the epidemic.

The high school escaped with only 2 cases. This was not unusual in view of the greater age of the children, of whom a large percentage were probably immune.

Shorewood contains 3,554 families. Including preschool children, a minimum of 2,760 who had not had measles are estimated to have been protected from it by these control methods.

FORMS OF FAMILY COÖPERATION

In this emergency, the right arm of the Health Board was the public health nurse. The task of Mrs. Hansen was to establish communication with every affected home and impress the necessity of strict compliance with the program. The usual way is by personal visits, but since practically every Shorewood home has a telephone the nurse was able to give the special instructions and orders to every family without leaving her office. There were no exceptions to the proffers of coöperation, and all requests were complied with to the letter. This allowed the nurse additional time for centering on the investigational and follow-up tasks involved in controlling the epidemic. Had her time been given to home calls, it is obvious that a greater number of children would have escaped official observation and control, allowing a larger number of contacts to develop and complicate the situation.

Because the "health conscience" of Shorewood is highly cultivated, any apparent failure to report cases of communicable disease is likely to be revealed to the Health Department by neighbors, upon the righteous assumption that official rules should apply to all families alike in furtherance of universal protection.

OBSERVATIONS OF THE HEALTH COMMISSIONER

The methods which Shorewood found so effective in this epidemic are not to be branded as far-fetched or as suited only to our own local conditions. With school inspection, protection depends upon the school nurse in discovering the symptoms in the child, then in excluding the case. In facing this epidemic it seemed obvious that if measles was not to run its course in the village the further association of exposed persons, who have not had measles, with other susceptibles should be prevented. This could be done only by isolating all contacts before they could con-

taminate others or began to show any signs of measles at all. It is clear that this required treating those contacts as though they were actual measles cases. No state law is directed against the free movement of measles contacts, but our "honorary quarantine" proved as effective as an officially promulgated rule with a penalty clause.

The isolation of seemingly well children in such numbers led to the fear of possible interference with classroom work for these excluded children. This was avoided. Although the exclusion period for measles cases is 2 weeks, it was deemed feasible and safe in connection with the contacts to limit their exclusion to 10 days, this period to begin 7 days after the last exposure. Allowing, therefore, for Saturday and Sunday—non-school days—only 8 days of classroom work was to be lost. But these children, not being ill, were permitted to continue their studies through home work supplied by the schools. From the educational standpoint, therefore, no school work actually was lost by these excluded pupils.

The success of this effort for the control of measles was fundamentally due to the thorough education of the public which the epidemic hastened. The telephone call to affected homes was an important factor in enlightening parents upon the special duties enjoined upon them by the health authorities. Use also was made of special issues of the Health Department's monthly bulletin, which were sent to every home. In these communications it was admitted that such a drastic method of control would be of no avail, and in fact carried an element of danger of spreading the disease, unless parents realized the responsibility imposed upon them and kept children from contact with all others for 10 days. In our bulletin of January 24 we ventured to predict that with such coöperation the epidemic would be terminated in 30 days. This was the fortunate outcome.

It is my conviction that with a proper educational foundation among all families, any community can establish control over its susceptibles and cut off a budding epidemic. From the standpoint of epidemiology there is nothing technical nor impractical about it, but it does necessitate a more or less complete understanding by heads of families of the purposes in view, and unanimous backing of the health department in carrying them out.

The Health Problem in Mexico*

RAFAEL SILVA, M. D.

Chief, Departamento de Salubridad Publica, Mexico City, Mexico

THE American Public Health Association, since its birth, fifty-eight years ago, has made many valuable contributions to the cause of public health. In the year 1891 a Mexican delegation representing the Federal District and several states of the Republic attended the meeting at Kansas City, and it was decided that the next convention (1892) should take place in Mexico. From that date, a group of Mexican hygienists have formed part of the Association. Twice, in 1892 and 1906, the City of Mexico has had the privilege of being chosen as the meeting place for your conventions, and Mexico City on those occasions threw its doors open enthusiastically to receive the members.

Since the time of that last joint meeting, your nation was involved in the greatest of wars; and our nation has passed through a long period of suffering. Our friendship has stood many proofs and now, with the utmost pleasure, we come to this magnificent and prosperous city of the State of Texas to seal our everlasting friendship.

International understanding and international coöperation are indispensable to all. Today, with the means of speedy transportation in use, isolation is not possible, commerce and industry unite us with solidarity, while intellectual longing for truth and spiritual needs of beauty lead us to search in other countries wider and wider horizons. Superior minds turn toward a brotherhood unlimited by political and racial boundaries and to an effort for knowledge and understanding devoid of prejudice.

It is for these reasons that I have cheerfully accepted this invitation to expound our achievements and our aims in public health. This is not by any means an easy task. Allow me to recall the words of Dr. Franklin C. Robinson on the occasion of the 1906 convention in Mexico City: "It is a sign of the times," he said, "that associations and societies are impatient at long presidential addresses. They seem now as out of place in gatherings like this as the old long sermons and prayers would seem in a modern church service. And this is not

* Read at the First General Session of the American Public Health Association at the Fifty-ninth Annual Meeting at Fort Worth, Tex., October 27, 1930.

trol of venereal diseases. In my mind the recognition of prostitution creates a wholly unsatisfactory state of things, admitting an unjust difference between the sexes.

Our department conducts a Division of Hygienic Education and Propaganda. People from all social classes are gathered to receive education by films and lectures, while mothers' clubs and other associations are constantly asking for health education material, which we deliver daily. Posters, folders, radio talks and written articles for the newspapers are distributed and we have had the satisfaction of co-operating with the border states of the American Union in sending articles for the Spanish newspapers and in furnishing our written propaganda for distribution among the Mexican laborers who live in this country. This division of education has been active in coöperating with the National Committee against alcoholism.

Our work on child hygiene is not easy to recount in a few words. Perhaps we have not attained all of our aims because child hygiene is still divided between two different authorities: the Department of Health for the first and second infancy, and the Secretary of Education for school hygiene. Antenatal and postnatal work is taken care of by our free clinics established throughout the Republic and by our visiting nurses whose work in the proletarian homes is of first importance. The National Association for Infant Welfare, a private organization, subsidized by public funds, assists us in an active way, and has opened free maternities and day nurseries which have proved to be valuable agencies in reducing our child mortality. In the recent Pan-American Congress of the Child held in Lima, Peru, this work was favorably commented upon and our country was chosen as the seat for the next Congress.

In the Division of Food Hygiene (which unfortunately only has jurisdiction over the federal district), important work has been done in improving our milk supply. Pasteurization has been enforced, the tuberculin test is used on the cattle, and veterinary inspection rigidly eliminates causes of contamination. Bacteriological and chemical control is applied and the sanitary conditions of stores handling this food are constantly being watched. Meat, eggs, fish and other edible foods are also inspected by suitable methods in markets and stores.

The Division of Drugs and Chemistry is in charge of supervising the purity of drugs and of the campaign against illegal traffic in narcotics; a Committee on Patent Medicines and Proprietary Preparations endeavors to eliminate nostrums and frauds.

Our Division of Vital Statistics has been endeavoring to secure information from a wider source than heretofore. Many areas in the

Republic are still without adequate medical service; we have not yet enforced the extension to the whole Republic of the Federal Sanitary Laws in respect to notification of transmissible diseases because we have not yet reached complete accord with local authorities on the enforcement of these laws. It is for these reasons that we have no morbidity statistics of the whole Republic. In those places where a Federal Delegation functions, we are securing data. These comprise nearly all the important cities, the ports and the border towns. Mortality statistics are collected from certificates of death. These are defective in places where there are no regular physicians practising, because of lack of proper diagnosis, introducing a source of error.

It must be borne in mind that the Federal Sanitary Laws are recent. In 1917 the Constitution of the Republic was reformed, creating the Federal Department of Health. The old Board of Health of the Federal District was converted into a Federal Department, but the struggles of that period delayed the approval of the Federal Sanitary Code which was approved and published in 1926. It is easy to imagine that it was not everywhere well received as it created a source of friction between local and federal authorities, but it was a necessary measure in view of the insufficient work done by the local authorities.

Our aim now is to follow up our work for a better coöperation between state, municipal and federal authorities, uniting our efforts and organizing a combined plan for the establishment of sanitary units. This organization, which will eventually solve many health problems, will comprise the federal delegation in the capital of the state, the municipal units and the elementary units which are to be established in every town, with a fundamental educational basis, on which rural hygiene and sanitation will be founded. The technical direction of the Federal Department is the key for organized scientific health work, but coöperation of local authorities is necessary in order to supply the towns with all the services. Good water and proper sewerage are needed in many communities, particularly in the tropical regions, but this will be slowly attained because of the scarcity of funds available in the municipalities.

Among the branches that need development in our country, Sanitary Engineering is the branch which most needs more expenditure of money.

When a country is sparsely populated, natural resources have not been developed, and a large part of the population lives on low living standards, the problems are difficult to solve.

Our government, now under the guidance of President Ortiz Rubio, understands the prominent place of public health as a basis for any

other activity, and education of the laboring masses, together with the development of roads, irrigation projects and many other far-reaching efforts for the development of our wonderful natural resources will lead us some time in the future to a better life of peace and happiness.

The betterment of our knowledge in hygienic science is the basis for a better service to our country, infinitely loved.

We come here in search of enlightenment, which in the end will serve our people's cause. United, we will meet the needs and desires of our countrymen working in harmony for the good of all.

Sight-Saving Review

ELIHU ROOT has been elected Honorary President of the National Society for the Prevention of Blindness, it was announced by Lewis H. Carris, Managing Director of the National Society for the Prevention of Blindness. The post was made vacant by the death of the late William Howard Taft, who had been Honorary President from the beginning of the society in 1915 until his death last March.

The publication, in the near future, of a quarterly magazine, *The Sight-Saving Review*, devoted to all aspects of prevention of blindness and conservation of vision, was also announced by Mr. Carris. "The new journal," he said, "is designed to meet the needs of state and local prevention of blindness workers, educators, illuminating engineers, school physicians and nurses, safety engineers, public health administrators, industrial physicians and nurses, sight-saving class teachers and supervisors, ophthalmologists, and anyone interested in the sociologic phases of saving sight."

The Sight-Saving Review will contain original articles, abstracts from current periodicals throughout the world, book reviews, and reports of the society's activities. Mr. Carris is Editor and Isobel Janowich is Managing Editor.

The Decrease of Tuberculosis in Mexico*

FRANCISCO DE P. MIRANDA, M. D.

Departamento de Salubridad Publica, Mexico City, Mexico

A DECREASE in the tuberculosis morbidity and mortality is observed in nearly all parts of the civilized world. This fact has been repeated and needs no demonstration since figures are easily available from many parts.

Mexico City statistics, notwithstanding the abnormal conditions through which we have passed in the last 20 years, show a steep decrease comparing favorably with that experienced in many large cities.

From a mortality of 500 per 100,000 inhabitants in 1900 we have reached a figure of 130 per 100,000. Compared with the mortality from all causes we can see that deaths from tuberculosis were 9.09 per cent of the general mortality in 1900, and 5.2 per cent in 1929.

Is this decrease due to efforts particularly directed against tuberculosis? Dr. Bermudez, Director of our Public Health School, has directed our attention to this problem, raising the question of the real value of a special antituberculosis campaign.

Though we have followed with great interest the advancement of methods employed against tuberculosis, the conditions in our country have been such as to limit our activities in all fields where great expenditures of money would have been necessary.

It was not until the economical status of the Federal Government improved that plans could be carried into effect to provide the means for such a campaign. It was last year that sufficient dispensaries devoted exclusively to tuberculosis were opened to the public. Before this tuberculosis patients attended the clinics of general medicine of the Welfare Board, and those considered as a source of contagion were isolated in the General Hospital or at their homes. The sanatorium for curable cases of tuberculosis will soon be completed. We can therefore say that, apart from the measures adopted against all contagious diseases, no special measures were taken until very recently.

Many health authorities claim that the decrease in the tuberculosis figures is due directly to the special measures taken. Is this a fact? It has appeared to us that the City of Mexico situation would throw

* Read before the Health Officers Section of the American Public Health Association at the Fifty-ninth Annual Meeting at Fort Worth, Tex., October 27, 1930.

light on the relative value of antituberculosis measures and this has decided the presentation of this paper. A review of the possible factors contributing to this decrease in this special case will be of some value in this respect.

We cannot speak of a Mexican race. The error of adopting the term "Mexican" as indicative of a race has been repeatedly made in the United States where many statistics place the term "Mexican" alongside of "Negroes." "Chinese" and other terms properly used as indicative of a race.

Someone has said that the Mexican is not a Mexican. This paradoxical statement has been made in the sense that the Mexican may be white, Indian, mestizo or even Negro. Of course the word Mexican has a meaning: it means a nationality and not a race. Unfortunately in our mortality statistics we have not made a racial study, and in the statistics collected concerning Mexicans in the United States no race differentiation has been made. We do not even know the percentage of whites, mestizos and Indians emigrating from Mexico to the United States. Pure Indians as a rule do not emigrate, as they rarely segregate from their tribes. The white Mexican emigrates sometimes, but as he generally is in a better economical position in his own country, I imagine that the percentage is not in proportion to that found in our cities. This leaves as a probability the bulk of the Mexican population of the United States as composed chiefly of mestizos in a larger proportion than that found in our cities.

On the basis of statistics published in the United States, the statement has been made several times that the Mexican is highly susceptible to tuberculosis. We must try to see if this statement is true in a general way or even in a restricted sense; that is, saying that he is highly susceptible in the United States or in certain parts of the United States, we shall try to solve the cause of this susceptibility, if it is a racial or an economical, or an educational problem. On the facts we have at our disposition, we cannot find sufficient evidence to prove the general statement. Without the bonds of prejudice we cannot speak of a racial predisposition when, as I have said, no race statistics have been gathered. Even supposing that the great majority of the Mexicans living in the United States are mestizos, we do not know in what proportions the white and the Indian races are mixed. It may seem logical to accept as valid for the Indian what has been said of the American Indian or the Negro, but there is not sufficient ground for this generalization. Even in that case we do not know if the susceptibility is a true racial characteristic.

If we admit that there is a racial relative immunity of the white it

has to be explained. We cannot admit that the difference in race susceptibility is the result of natural selection, because probably all races are equally old on the earth, and they have been all alike subjected to the same natural selection. It has also been said that our education and civilization, with all our health work, works against the results of natural selection and not in favor of it. We, then, can think that civilization is preserving the feeble and not the strong, while modern and "civilized" war effects also a selection contrary to natural selection, as we are now sending to war and death the strongest men of our countries.

We could on the other hand think of an acquired immunity to tuberculosis which would be at the same time hereditary in character. It has been repeatedly said that acquired characters are not hereditary and, on the contrary, in relation to tuberculosis it would be easier to prove that there is an hereditary predisposition, as the sons of tuberculous parents are more predisposed to this disease. It has also been said that tuberculosis is recent among the colored races and this recent contamination has been pointed out as an explanation for the pretended susceptibility. If we are to accept this we would expect to find a greater susceptibility in the white race, enfeebled by a past record of heavy tuberculous infection.

Recent opinions expressed by such an authority as Calmette lead us to be more careful still in regard to acquired immunity to tuberculosis. Speaking about the interpretation of the Pirquet test, he points out that immunity to new infections exists as long as there are present in some part of the organism some causative agents living in a sort of symbiosis with the defensive cells. If this is to be admitted, we cannot expect to have an hereditary immunity to tuberculosis. The frequency of low grade infections in early life, as found by the Pirquet test, accounts for the acquired immunity in adults.

The Mexican Indian had, as a rule before the conquest, a higher grade of civilization than the Negroes in Africa. They did not live

only in scattered tribes, but formed communities some of which were cities of certain importance. We do not know certainly whether tuberculosis was present among them as we know of syphilis, or whether it was brought to Mexico with conquest. Anyway, there was a degree of human intercourse not comparable to that of other races, except the white. The Conquest was not only a war affair, but also a penetration that eventually led to a mixture of races; so the conditions are not comparable with the American Indian. Nearly 400 years have passed since the contact of the two civilizations and races; so we cannot say that contamination is very recent.

On the other hand, we cannot speak of inherently feeble and strong races. Though the Mexican mestizo of today may seem feeble in his physical organization to the passing observer, if we study the characteristics of these men we find certain qualities that may be surprising. The Indian is less subject to cancer, obesity, gout, chronic rheumatism, migraine, arteriosclerosis, chronic nephritis, and all those diseases that statistics show to be increasing in the white race. In regard to focal infections such as pyorrhea, tonsillitis, appendicitis and gall bladder infections, he is at a distinct advantage. His muscular development is not great, he is not of the unphysiological Sandow type, but has considerable endurance and, properly fed, he may compete in Marathon races using his customary sprint. We simply do not know the possibilities of this race when placed on a favorable economical and educational basis.

Returning to the issue in question, Mexico City statistics show the question of race susceptibility of the Mexican cannot be taken seriously into consideration. Race susceptibility is not a factor that can be modified in one generation.

Climate must be considered principally not in itself, but taking into consideration the personal and racial adaptation. The climate of Mexico City has all the advantages in relation to tuberculosis. Although within the tropical zone, it has an altitude of 7,350 feet. This explains its temperate climate, nearly even all the year round. The sun shines nearly every day and its rays are extraordinarily rich in ultra-violet radiations. This accounts for the rarity of rickets and tetany. The metabolism of calcium is thus favored with its beneficial effect on the process of healing of tuberculous focuses. The non-existence of tropical diseases such as malaria and hookworm, and the rarity of amebic dysentery in comparison with the lowlands, are factors in the sense that all these diseases contribute to predispose the individual to tuberculosis. High altitude is not a cause of organic trouble because it is easily compensated by increase in the red blood

cells. Pure Indians inhabiting the Sierras of Mexico and Puebla have more than six million red blood cells per c.m.

Speaking about predisposing ailments, in Mexico City gastro-intestinal troubles may be important factors, as we still have a high mortality and morbidity from these. Better hygienic education of the people can do much to correct these, as nearly all these diseases are due to errors in diet.

This brings me to the main point in prevention of tuberculosis. To my mind the most important thing to be done against tuberculosis is to bring better standards of living to the community. This means not only charity. In Mexico charity has an extensive field. From the time of the Spanish domination the missionaries burned in the purest of human love. But charity, being a treatment for these conditions, does nothing or very little in the way of prevention. Many times we are reminded of that rich man who did many charities, but before that, had made the poor. Charity is the only excuse we can offer to those that have been made poor. There are many ways of ruining men, not only taking away from them what they already have, but depriving them of the opportunities for an education and even creating in their minds an inferiority complex, or, speaking in plainer terms, robbing them of hope and confidence. Hope and confidence in their earthly life—not only in a future unearthly life—is what the Mexican Indian needs.

Hospitals, medicines, and kind words are, of course, the least we can offer to those who do our dirty work, the dirty work that we whites do not want for ourselves. The kind of charity that does not make racial or national distinctions, that is not a blow to human dignity, and that we call Christian charity can do much to alleviate these conditions, provided it is intelligently directed in the way of prevention—and prevention in the widest sense, because we live in 1930 and not in 1530. The widest sense of prevention is not prevention within the limits of a city, a state, or a nation, but prevention applied in an unlimited way to humanity regardless of all limitations.

We live in the days of Rockefeller, who has founded a medical school in China, not in the days of the Peking walls. The health of Chicago may be important to sanitarians of that city; but the health of Texas is also important for them, as is also the health of Mexico, and this meeting is a proof for this statement.

The tuberculous predisposition of the Mexican is the tuberculous predisposition of the low wage earner, and the low wage earner of today has not been relieved by machines and labor saving devices, but has been made more miserable by them, because of unemployment.

Machines are a blessing to the greater part of humanity who have been taught to use them, but for those who have to compete with their own muscles and only with their muscles, life is hard today. The low wage earner is not only the common laborer or peon, but also the woman who hardly gets a living with hand-sewing, or the artist unable to sell his pictures. Mexico is making an effort to change labor conditions, not in the sense of Bolshevism, but in the sense of applying better labor devices, ending primitive conditions of agricultural practices, building roads and irrigation dams, in the measure of its possibilities. * 1

The education brought to the Indian in rural and village schools, and the sort of hygienic education that we are striving to spread, has given us some fruits, but we are not satisfied and will never be satisfied, as our longing is unlimited. We are trying to restore in the souls of the Indian and mestizo the self-confidence and self-reliance which were long ago lost on account of domination in war and peace, by the use of material and moral means of subjection, suppressing their dreams in a perilous way that sometimes produces explosions outside the channels of order and law. These are factors in the fight against tuberculosis.

Other improvements, in housing conditions, in municipal sanitation, in the production and handling of foods, principally of milk, always recognized as very important, have brought undoubtedly good results, as well as the old measures of isolation and disinfection which still have their place in the modern fight against this terrible disease.

I do not doubt that the Mexican mestizo or Indian when he comes to this country may seem predisposed to tuberculosis. He comes from a country of even climate to one of extreme changes, where the language and habits are different, and where he feels himself under the pressure of an enormous economical power with the tremendous wear and tear of a life that means struggle carried to its most terrific strain, where even noise is unbearable to those not adapted to it. He is not prepared to meet such conditions, and he may often crumble under them. Modern complication of things is becoming hard for all of us. But this is not a racial problem, it is an economical and educational one, something which is changeable in one or two generations.

Now, we have adopted a special plan to fight tuberculosis on modern lines, because we know of its real value, but we are also convinced that this plan is only complementary to that explained above.

May this paper meet with your open minds, contributing to a better understanding and sympathy for the solution of one of our greatest problems.

Flooding as a Method for Controlling Extensive Areas of Fly Breeding

H. LARA, M. D., DR. P. H., M. MA. AYCARDO, M. D., AND
M. ASUZANO, M. D.

School of Hygiene and Public Health, University of the Philippines, Manila, P. I.

THE employment of the principle of drowning in the extermination of fly larvae is not a novelty in sanitary science. Levy and Tuck¹ were the first to suggest the application of the principle. Their ingenious device for trapping fly maggots utilized the migratory habits of the maggots. They employed a manure-containing receptacle, which consisted of iron grating, or stout wire screening, of about $\frac{1}{2}$ inch mesh. Below the floor of this receptacle they placed a container with several inches of water, with or without poison. The maggots, in their wanderings; would drop into the water, and be drowned.

However, so far as our knowledge is concerned, our report relates to the first purposive attempt by man to control extensive areas of fly breeding by the extermination of larvae by drowning.

In order to make our experimental work more readily intelligible, it seems advisable to detail briefly the situation with which we were confronted. During the first two weeks of February, 1929, an enormous development of a species of alga, termed "lia" in Tagalog, occurred in the waters of Laguna de Bay, a lake about 10 km. southeast of the City of Manila. Great quantities of this aquatic plant had been deposited by the receding water over a large area extending along the western basin of Laguna de Bay, and certain portions of the bank of the Pasig River, and its tributaries. The area covered by this thick film of "lia" comprised a stretch of level land about 25 km. long and nearly 50 m. wide, extending along the edge of the water of the lake.

Upon dying, the aquatic plant ("lia") emits an obnoxious, fecal odor. The result of this was that swarms of adult house flies were attracted. In the decomposed algal material, and in the soft bed of earth and mud coated with a layer of decomposed lia, the females laid their eggs. An ideal breeding place for flies resulted; and the innumerable eggs which had been deposited hatched and developed into young maggots. As adult larvae, they issued from the decomposed

lia, and, seeking the nearest point at which they could enter the soil, burrowed down into the mud to pupate.

As a result of the above situation, a fly nuisance developed during April and May, 1929, which was unprecedented in the history of the Philippines. In the regions bordering the Laguna de Bay flies were present in such pestilential numbers that the inhabitants were compelled to eat their meals under mosquito bars, and United States Army horses in the affected area were compelled to wear masks for protection against the swarms of voracious flies.

The extensive fly-breeding area along Laguna de Bay affected the City of Manila to no small extent. The insect population of the city rapidly became augmented by numerous flies that came from the breeding places in the Laguna de Bay shores, notwithstanding the 10 km. which intervene between the two points. Traffic by land and water was chiefly responsible for facilitating the immigration of numerous flies into the city. We observed that boats, carts, and trucks of fruits and other merchandise, afforded shelter to adult flies, and brought along with them large consignments of the pests. The insects cling to the sides of bull carts, carromatas, automobiles, auto-buses, and even on the backs of animals and men that passed through or near the affected region, and thus were transported to the City of Manila and contiguous areas.

As soon as the fly situation had become a distinct nuisance, the people living in the towns near the Laguna de Bay suspected, and claimed, that the many tons of decomposed algae, which had been spread uniformly in a film of considerable thickness over the shore of the lake by its receding water, were the breeding ground of the flies. By the early part of May, 1929, the authorities had come to accept the truth of this. In view of the extreme seriousness of the situation in Manila and its environs, and because of the ineffective eradication measures that were being applied in the city against the countless adult flies, the School of Hygiene and Public Health was led to conduct an intensive study of the most practical and effective method for controlling, or at least arresting, the development of the pests in the early and most vulnerable stages of their life cycle in the breeding areas.

EXPERIMENTAL FINDINGS

From May 11, 1929, laboratory and field experiments were conducted for the purpose of finding an effective and practical method of exterminating the incredible multitudes of fly eggs, larvae and pupae in the breeding places along the shores of Laguna de Bay. The following were tried:

Spraying with Chemical Solutions—Several areas of fly-breeding, each 3 m. square, were outlined (Figures I and II). One square was sprayed with a 5 per cent solution of cresol, a second with a solution of clenral (sodium hypochlorite solution), and a third with petroleum.

FIGURE I—Spraying with chemicals a limited fly-breeding area

FIGURE II—Limited area of fly breeding preparatory to burning

Spraying with chemicals was found to be impractical, due to the high cost of materials, as well as of labor. To be effective, the soil must be thoroughly covered, or soaked, with the chemical solution, and the cost of spraying the whole breeding area would have been prohibitive. Unfortunately, they did not resort to the use of borates, as borax or calcined colemanite.

Burning—A portion of the breeding area 3 m. square was covered with rice husks (ipa), sprayed with kerosene, and set on fire. Another area was covered with dried shrub, and ignited. The burning method proved unsatisfactory and impractical, mainly because no suitable inexpensive material that would burn uniformly, thoroughly and sufficiently long was available. Moreover, the changing direction of the wind and the humidity were disturbing factors.

Stamping—Another spot was selected and allowed to be stamped by animals and man. This method likewise proved unsatisfactory; besides being slow, the stamping process could not be applied uniformly and effectively. Because of the softness of the area, it was found impractical to employ a road roller, or other convenient means of applying heavy pressure.

Surface Scraping—An attempt was made, in a limited area, to scrape the infested surface and then to bury the material, or dump it into the water. This method, too, was found to be impractical on the large scale required, because of its slowness, costliness, and the enormous amount of manual labor required.

Flooding—The above methods having been found to be impractical, it was decided to endeavor to drown the developing flies by flood-

ing the infested area with water from the lake. This method was found to be effective, economical, rapid and practical.

A low earth and mud dike, constructed from the materials on the spot, and enclosing a fly-breeding area of about 850 sq. m., was constructed in the fashion illustrated in Figures III and IV. It took 3 men only about 1 hour to build a dike 85 m. long and considerably thicker than was actually necessary to hold the water in place. Then, by the use of an old fire-engine rotary pump of 500 gal. capacity per minute, kindly loaned and manned through the courtesy of Engineer Santiago Artiaga, Acting Mayor of Manila, and Chief Vanderford of the Manila Fire Department, the enclosed area was flooded with water from the lake by way of an artificial canal dug for the purpose (Figure III).

It took less than 1 hour to flood the 850 square meters of experimental area. Upon inspection 7 hours after flooding, longer than necessary to drown the fly larvae and pupae, the area was still well submerged. Laboratory observations of pupae collected from the submerged area showed that all of them were killed. In fact, all of the pupae which were held imbedded in the soil of the flooded area—and these comprised the majority—were drowned, although it is probable that certain of them which floated to the surface lived to become adult flies. Experimentally, we determined that no normal pupae, obtained from the unflooded area, were able to survive complete immersion in water for 3 hours under laboratory conditions.

FIGURE III—Area of fly breeding flooded, showing dikes, canal and pit for bringing in water inland

FIGURE IV—The diked fly-breeding area under water

For the flooding of the entire fly-breeding area, labor could have been minimized, and much time saved, by mounting several centrifugal pumps on floating rafts which would have been movable in any direction in the water. The employment of rafts would have eliminated labor expense in canal digging, to which we had to resort in our experiment in order to operate our heavy pump on firm land.

DISCUSSION

In the Philippines, unlike the countries of the temperate zone, there are only two seasons, the dry and the wet. The census of 1903² has this to say about thermic conditions in the Islands:

There are three different thermic conditions met with in the Islands. At some points the temperature is rather high throughout the year, the annual variation being but small; at others the temperature is always sufficiently temperate, varying only little during the year. Other places finally combine the characteristics of the two preceding classes, being hot during one part of the year and temperate during the other; they have thus two seasons.

As temperature is admitted to constitute one of the most important regulatory factors in fly development and prevalence, we include Figure V, for the purpose of giving an idea of the annual temperature variation in Manila and its environs.

It is to be noted that the atmospheric conditions during the rainy season are not necessarily unfavorable to fly development. Hence, it follows that there are flies all the year round in the City of Manila and its environs, but they are more abundant during the dry or hot season than the rainy season. This is largely due to the fact that, during the rainy season, the greater part of the potential fly-breeding places in the environs of Manila becomes submerged. A large proportion of eggs deposited in these areas during periods of dryness are affected unfavorably, because even if the eggs hatch, the probabilities are that the larvae will be drowned when the breeding place is flooded.

This is the principle upon which our experiment on artificially flooding a fly-breeding area was based; we merely took a leaf from the notebook of nature. In fact, our investigations of the conditions under which the flies had been multiplying enormously during the summer months, as well as our studies upon the practical methods of control, were commenced too late. After we had proved to our satisfaction that artificial flooding of a limited area was feasible, and we

FIGURE V—Annual variation of the temperature at Manila (1880–1902)

had received an estimate from engineers that for \$7,500* the whole fly-breeding area along the shore of the Laguna de Bay (25,000 m. x 50 m.) could be effectively and quickly controlled by the flooding method, nature stepped in and completed the experiment for us. The advent of the rainy season, with very heavy rains, resulted in the wholesale drowning and extermination of the innumerable larvae and pupae in the extensive fly-breeding area, but not before the extreme fly prevalence had inflicted marked suffering and exacted its toll of priceless human lives, in municipalities around Laguna de Bay, from gastrointestinal diseases. While it is true that the reduction in the number of flies might not have been exclusively due to the rain flooding the fly-breeding areas, there can be no doubt that this was an extremely important factor.

In conclusion, we would suggest that a trial of the artificial flooding method, with certain necessary modifications, might be worthy of consideration in the control of fly breeding so commonly seen in extensive garbage and manure dumping grounds of such tropical cities as Manila. It might, perhaps, be tried wherever water is readily available, in lieu of the method of spraying small amounts of disinfectants in and around the city. This latter method is not only costly, and time-consuming, but, as now practised, it does not yield very satisfactory results. Repeated observations made by one of us (H. L.) have shown that, in spite of spraying the surface of garbage heaps with disinfectants, the decomposed materials are teeming with maggots about 3 in. below the treated surface. The spraying of disinfectants is ineffective, unless the breeding ground is thoroughly soaked with the disinfecting solution. Flooding the place with water alone, and drowning fly maggots, would seem cheaper and more practical than the spraying of small amounts of disinfectants, which are ineffective in most cases. Moreover, covering the refuse material with water alone once a week might hasten decomposition, which the addition of disinfectants tends to delay. Earlier decomposition results in earlier settling down and more rapid conversion of the material into soil.

In considering the possibility of fly control by the application of the flooding method in garbage and manure dumping grounds, it is essential that the breeding area be completely submerged with water for at least $2\frac{1}{2}$ to 3 hours, after adequate preliminary arrangements have been made for holding the water. The operation should be repeated at least once a week, until no more signs of fly development are noticeable.

* It is believed that the cost of control operations could have been further reduced if volunteer labor could have been procured from among the people of the affected region

SUMMARY AND CONCLUSIONS

1. This report is concerned with the experimental efforts at control of an unprecedented area of fly breeding along the shores of Laguna de Bay, a lake about 10 km. southeast of the City of Manila. During the first 2 weeks of February, 1929, an enormous development of a species of alga occurred in the waters of this lake. With the recession of the water, great quantities of this aquatic plant were deposited in a thick film over a large area extending along the western basin of Laguna de Bay, and certain portions of the bank of the Pasig River and its tributaries.

2. During April and May, 1929, this decomposing algal material furnished an ideal breeding place for flies, which resulted in a nuisance unprecedented in the recent history of the Philippines.

3. Beginning on May 11, 1929, laboratory and field experiments were conducted for the purpose of finding an effective and practical method of exterminating the incredible multitudes of fly eggs, larvae and pupae in the algae along the shores of Laguna de Bay.

4. In experimental areas, it was found that spraying with chemical solutions, burning, stamping, and surface scraping were impracticable and inefficient methods of fly control.

5. However, it was found that complete flooding with water of 850 sq. m. of breeding area resulted in the drowning of the great majority of the larvae and pupae.

6. The validity of our experimental demonstration of fly control by flooding was strikingly proved by the fact that shortly thereafter the rainy season commenced, and the flooding of the entire breeding area resulted in the complete control of the fly nuisance.

7. It is suggested that a trial of artificial flooding, with certain necessary modifications, might be worthy of consideration in the control of fly breeding so commonly seen in extensive garbage and manure dumping grounds of such tropical cities as Manila.

ACKNOWLEDGMENTS—Our sincere thanks are due Dean Edward R. Hyde of the College of Engineering of the University of the Philippines and Paul W. Mack, Chief Engineer of the Metropolitan Water District, for valued coöperation and aid.

We are very grateful to Dr. Wade W. Oliver for his kindness in going over the manuscript and offering many helpful criticisms and advice in the preparation of this paper.

Typhoid Fever Epidemic in a Leper Hospital

LEE S. HUIZENGA, M. D., DR. P. H.

Mission to Lepers, 20 Museum Road, Shanghai, China

IN June, 1929, a number of patients of the Taikam Leper Asylum, on Taikam Island, South China, developed an acute disease to which at first little attention was paid, but when one case after another developed, word was sent to the mainland to those in charge of the asylum. Fear spread among the Chinese directors and assistance was delayed. Just at that time we were making an inspection tour for the American Mission to Lepers. While in Canton, we heard that already one-fourth of the population had come down with the dreadful epidemic. The only attendant described the disease as an acute intestinal disturbance, lasting but a few days after it had progressed to tenesmus of the bowels. Nothing was said of the fact that the patients did not feel well for a long time previous to this final state. With the help of the Public Health Officer of Macao, and another noted physician of that city, we hastened to the island on a government customs launch for an investigation.

Before taking up in detail the epidemiological investigation it is necessary to discuss briefly the general plan of the institution.

The main buildings, constructed of stone with but little provision for ventilation, consist of 12 one-story dormitories, a church and administration building, a hospital, and kitchen, all built on a square 300 by 300 feet. Each dormitory, 50 by 33 feet, is built to accommodate 16 to 20 lepers. The buildings are close together and narrow streets lead from one to the other. They are located in a small cove on the island.

Taikam Island is about 3 miles long and its greatest width is $2\frac{1}{2}$ miles. It is mountainous throughout, and covered with underbrush. A ridge divides it in two parts. Streams, springing out of the ridge, supply each side separately. Each stream flows into a small bay, one to the south, called South Bay, and the other to the north, called North Bay. North Bay has two coves on which the leper hospital is found. South Bay has a large fertile valley which is occupied by sea pirates. Between the pirates and the lepers there is no communication, although the whole island technically belongs to the leper colony. The

absolute segregation of the lepers and the separate water supply for the two groups of inhabitants are of importance for our epidemiological study.

A beautiful stream of clear water supplies the leper colony. If properly guarded this would be sufficient for water and power. As it is, it is a source of great danger. Gardens above the colony are watered by the stream. Night soil from the colony is used for fertilization and the watershed is not protected.

Clothing too was washed in the stream above the place where the cook got his water for the kitchen. Latrines were built over the stream below the colony, and a shellfish bed in the bay thus became contaminated. Human feces were found strewn over the premises. According to Chinese custom, men and women were washing their clothes in the stream and others were beside them washing their teeth.

Upon investigation we found that about two months earlier a new group of lepers had been admitted to the colony and were put into the wards at once without the regular period of quarantine that should be observed in such institutions. After 2 weeks one of the new patients came down with the disease, and from that time on one after another was taken sick until no less than 52 of the 200 inmates had died of the disease. The only attendant present beside the lepers was a nurse who had had some training in leprosy but did not know the least thing about any other diseases.

We examined 4 of the patients still ill and soon came to the conclusion from clinical observations that the disease was typhoid fever. There was no laboratory; hence no microscopic examination could be made. We learned that the excreta of the patients had been thrown outside, and had undoubtedly found its way into the water supply, contaminating both the water used for cooking and the oyster beds. An interesting fact is that not one of the pirates came down with the disease, although their village is within a mile of the leper village, but, as explained, with an entirely different water supply and with no direct contact with the lepers in any way.

Epidemics of this sort rarely break out among leper patients owing to the isolation usually maintained. After the proper precautions were taken and the caretaker was properly instructed, the epidemic soon subsided, but at the expense of many lives.

Owing to the fact that there was no physician and not even a graduate nurse on the grounds, it is impossible to give exact figures. There were at least 60 cases of typhoid fever, of which only 3 are known to have recovered, though 5 are said to have done so. It is certain that 52 out of the 60 cases died.

WHITE HOUSE CONFERENCE ON CHILD HEALTH AND PROTECTION

THE impression gained of the recent White House Conference* depended largely upon whether it was viewed telescopically or microscopically. In its broadest aspects it presented a galaxy of stars of varying magnitude, clustering about four main nucleuses—medical service, public health, education, and care of the handicapped. Within each group, the data with which it was primarily concerned had been thoroughly sifted. The wealth of material was condensed and brought into order and cohesion. Several comets and a few nebulae did not intercept the main orbit of the Conference. The only threatened interference occurred when the transfer of the child health work of the Federal Children's Bureau to the U. S. Public Health Service was recommended. The conference took no formal action on this controversial matter and it was referred to a Continuation Committee. The final complete reports of the Conference will undoubtedly be encyclopedic. They should furnish us with basic data for many years to come.

Viewed microscopically there appears to be very little, if any, new material contributed by this Conference. The existing data have been compiled and analyzed as never before, and guiding principles have been evolved. The scientific committees have been very cautious in erecting new standards and have requested more time to complete their

* See Child Hygiene Section

work. Basic needs certainly have been stressed, and the necessity for better administration clearly pointed out. The whole child in his many sided relationships now stands as a challenge to all those interested in his welfare.

At present the practical outcome of this Conference cannot be measured. It depends upon how largely local groups will be stimulated to apply scientific technics now at their disposal. Sound administrative procedures and ample funds are absolutely essential. Continuation groups and regional child health conferences are now in order.

SMALLPOX AND VACCINATION

THESE subjects are matters of perennial interest, especially to the citizens of the United States, which country has made such a bad showing in their control.

A recent report,¹ while presenting little that is new, discusses almost all factors concerning smallpox and vaccination. The facts have been collected from more than 20 countries and make up a survey of the practices and results obtained.

The first question considered is nomenclature, in the discussion of which many statistics are given as to the number of cases and deaths. With 3 exceptions, the death rate has been extremely low, and in only 1 case did the death rate reach the old-time figures. The conclusions drawn are that the generic name *variola* should be recognized as describing two varieties of the disease—*variola major* and *variola minor*, under the latter of which *alastrim* should be placed, with full recognition that it is not a distinct disease, but a mild type of smallpox; that the division is largely an epidemiological one; and that we are attempting to discover whether the two types are interchangeable.

Perhaps of more importance is the second question, which concerns postvaccinal encephalitis. A careful study of the condition in England and Holland, the two countries which have suffered most from this sequela, has been made. It must not be forgotten that we have been obliged to recognize encephalitis following vaccination in this country, some 20 cases having been reported, of which 3 have been confirmed by anatomical and pathological examinations. Unfortunately, the studies have not showed the prevention, but it is recognized that this condition follows the use of the viruses of many different strains in Europe and elsewhere.

The third part of the study is concerned with vaccination, under which we find the discussion of instruments, methods, cleansing of the

field of operation, dressings, concentration and control of viruses, purity and revaccination. It is perhaps needless to add that there are variations in regard to almost all of these. There is a general tendency to early vaccination, and glycerinated virus is used by preference. Most countries control contamination rigorously by bacteriological examinations for aërobic and anaërobic organisms. Dressings are not recommended officially. The choice is left to the physician in many cases. After our American experience with tetanus following the use of shields, one should be very careful in the employment of dressings. Simple gauze for protection is advised in some countries. There has been a surprising lack of experiments on the preferable methods of vaccination. Scarification is still used in many countries. In the United States it is believed that the best practice is that recommended by the U. S. Public Health Service—multiple pressure with the needle.

The figures on the results of revaccination are more interesting. In many countries it is not obligatory, although advised at periods varying from 5 to 7 years, and always in the presence of an epidemic.

We have long held and expressed the opinion that much damage has been done by the lack of insistence on revaccination. Too often has it been taught that a single vaccination protects throughout life. The data given in this report show most clearly the importance of revaccination, the percentages of successful retakes being from 45 to 95, very few countries reporting below 50.

It is impossible to give too much study to these matters and often rule-of-thumb methods taught during the medical course are followed. We cannot urge too strongly upon physicians and health officers the importance of vaccination and revaccination, employing the best methods and the best virus.

RECORD FORMS FOR PUBLIC HEALTH WORK

IT has long been recognized by "big business" that administrative methods are notoriously behind manufacturing and production methods.

Public health is a "big business" and its proper administration a problem to which much consideration has profitably been given. Its management, control and promotion have not kept step always with scientific and technical progress. More careful thought and planning are needed. Public health administration requires the development

of a special technic, and certain aspects of standard business practice can be adopted as part of that technic with little modification.

The keeping of adequate and accurate records, at a minimum cost in time and money, is one of the major responsibilities of every executive, in or out of public health. "Big business" is using standard office forms, and filing methods adapted to particular problems. Public health can do the same as a simple improvement in administrative methods.

The Committee on Record Forms has studied record-keeping in health departments for five years with the avowed purpose of developing forms that can be included as part of the special technic necessary to maintain and guide a smoothly-functioning, efficiently and economically-managed health department.

The Committee presents, through coöperation with Remington Rand Business Service, Inc., which organization is publishing and distributing the forms approved thus far, twenty-five record forms for use in health departments. They are described on page XIX of this issue.

The Committee will release other forms for publication shortly. In its work, it "has aimed to devise record forms that would keep to the smallest number possible, hold to essentials only, and would group these so that the facts could easily be taken from them for statistical purposes." The committee has "constantly and primarily kept in mind the problems of the health officer of the smaller community and his need for economy."

Here then, in these twenty-five published forms, we find a real contribution to the business methods of a health department.*

ASSOCIATION NEWS

GOVERNING COUNCIL MEETINGS AT FORT WORTH

THE Governing Council of the A. P. H. A. held four meetings at the Fifty-Ninth Annual Meeting in Fort Worth, all of them presided over by the President, Dr. A. J. Chesley.

One amendment to the Constitution and three amendments to the By-laws were adopted, as follows:

AMENDMENT TO CONSTITUTION

ARTICLE III, *Section A*, amended by the addition of the following at the end of the section.

6. A representative to be designated by each regional branch. Such representative shall be a Fellow of the American Public Health Association.

AMENDMENTS TO THE BY-LAWS

ARTICLE I, *Section A, Part 1*, 11th paragraph, amended to read as follows:

"The right to hold office or to serve as chairman of a committee in the Association shall be limited to the Fellows of the Association, whether Section Fellows or unaffiliated Fellows. The right to hold office or to serve as chairman of a committee in a Section shall, however, be limited to the respective Fellows in such section. This provision shall not prevent the election of a Vice-President of the Association who may not be a Fellow."

ARTICLE VI, amended as follows:

"There shall be at least one annual meeting of the Association, held at a place to be selected by the Governing Council. All papers and reports presented at the annual meeting and other meetings, including regional meetings, shall be the property of the Association for publication unless this right is waived by the Committee on Meetings and Publications. Special meetings of the Association may be called by a majority vote of the Governing Council, the Executive Board, or the Association."

The following amendment to be added at the end of Article I:

"If, in the opinion of the Executive Board, any member or Fellow of the Association be found (hereafter) to have permitted the use

of his name, or otherwise to have allowed himself to be quoted or used for illustration in the advertising of a commercial product, in such a manner as to reflect discredit upon the Association, his Fellowship or membership in the Association shall thereupon be terminated. The application of this article shall not be retroactive."

Eighty-two members of the Association were elected to Fellowship, and the following Life Members were approved:

Louis I. Dublin, Ph.D., New York, N. Y.
Edgar E. Hume, Boston, Mass.
Sally Lucas Jean, New York, N. Y.
Cornelia Lyne, New York, N. Y.
Stanley H. Osborn, M.D., Hartford, Conn.
Herman von W. Schulte, M.D., Omaha, Neb.
Marguerite A. Wales, R.N., New York, N. Y.

The Committee on Fellowship and Membership recommended Dr. Aristides Agramonte of Havana, Cuba, for election to Honorary Fellowship in recognition of his inestimable services in demonstrating the transmission of yellow fever and its control. This recommendation was adopted unanimously by the Governing Council.

The application of the Georgia Public Health Association for affiliation was also approved. This makes 15 state societies which are affiliated with the A. P. H. A.

In accordance with the constitutional provision that the Governing Council should receive from the Executive Board at the Annual Meeting of the Association a report on the work, accomplishments and financial status of the Association during the year preceding the Annual Meeting, and a formulated statement of a program of the major activities proposed for the ensuing year, the Chairman of the Executive Board presented his report, which will be pub-

lished in full in the *Year Book*. This indicated, among other things, that the financial condition of the Association is sound, the net asset value on August 31 being \$27,763.09, representing a gain of \$8,605.75 for the first 8 months of the year.

The following tables, which show the number of members in each of the 14 affiliated societies and the distribution

of members and Fellows in the sections, are also taken from Dr. Rankin's report.

At this time there was also approved the constitution and by-laws of the recently established Western Branch, which closely follows the A. P. H. A. constitution.

There was presented to the Governing Council a report of a conference held in Detroit, June 24, 1930, in which several

national organizations, including the A. P. H. A., had participated, relating to the development of an organization to be known as The American Committee for the Prevention of Deafness. This matter was referred to the Executive Board for consideration inasmuch as the idea was prevalent that there was already in existence an organization for the hard of hearing.

Montreal was chosen as the place for the 1931 Annual Meeting of the Association by written ballot on the report of the Sub-committee on Annual Meeting of the Committee on Meetings and Publications.

The Resolutions Committee presented 14 resolutions to the Governing Council, 8 of which were adopted, the others either being disapproved or referred to other bodies within the Association. The resolutions adopted dealt with the American Museum of Hygiene, the George Washington Bicentennial, the eradication of tuberculosis, Indian welfare, the safety of milk supplies, tick-borne diseases, political interference in public health work and deceased members. The resolutions in full will be printed in the *Year Book*.

The following officers were elected for the year 1930-1931:

President-elect—William C. Hafler, M.D.
First Vice-President—Rafael Silva, M.D.
Second Vice-President—J. W. S. McCullough, M.D.
Third Vice-President—Arthur H. Flicker, M.D.
Treasurer—Louis I. Dublin, Ph.D.

The report of the tellers was presented and the following Governing Councilors were elected for 3-year terms expiring in 1933:

C. E. A. Winslow, Dr.P.H.
Thomas Parran, Jr., M.D.
George H. Bigelow, M.D.
S. J. Crumbine, M.D.
John A. Amyot, M.D.
M. J. Roreau, M.D.
W. S. Leathers, M.D.
John Sundwall, M.D.
Livingston Farrand, M.D.
Emery R. Hayhurst, M.D.

This completed the business of the retiring Governing Council. Upon the adjournment of the last meeting, the new Governing Council convened, with the new President, Dr. Hugh S. Cumming, in the chair. There was also present at this meeting Dr. Rafael Silva, the First Vice-President.

At this meeting two members were elected to the Executive Board for 3-year terms, namely, Dr. Haven Emerson and Dr. John A. Ferrell.

CHILD HYGIENE SECTION

OUR readers will note with pleasure the revival of our Section on Child Hygiene, which has been inactive for the past year, owing to the fact that Dr. Merrill E. Champion, who conducted it so ably, was called to duties which demanded his entire attention. We owe a debt of gratitude to Dr. Champion.

The field was carefully studied before appointing a successor, and it is with great confidence and satisfaction that we are able to announce that Dr. Richard A. Bolt, Director, Cleveland Child Health Association, has consented to take charge of the work. Dr. Bolt

needs no introduction. He occupies a most enviable place in the special branch of medicine to which he has devoted his energies. His reputation is not confined to our country, but extends wherever children and their welfare are considered. Dr. Bolt has called to his assistance 12 specialists in child hygiene from different parts of the country. Under his guidance, we are assured that our *Journal* will carry the best and most carefully selected material on this subject.

The Editorial Staff, as well as the general membership of the Association, welcomes Dr. Bolt.

PUBLIC HEALTH ADMINISTRATION

HENRY F. VAUGHAN, D. P. H.

A Printing Division in a Health Department—The Milwaukee Health Department reports that it uses two multigraph machines which are operated almost continuously for the printing of forms and educational material used by the department. A skilled operator is employed for this purpose. Practically every blank form used by the health department, in addition to a considerable number of pamphlets and other educational leaflets, is prepared in the department's printing division. Electroplates are made for the routine forms which can be rapidly fitted to the multigraph machine and any desired number of forms printed in a very short time. There is not only a saving in expense, but the additional factor of rapid service at a time when it is most desired.

The department estimates that it saves in printing from \$5,000 to \$10,000 per annum over the cost of having the work done by a job printer. In addition to all blank forms, the department prints its own quarantine placards, all small dodgers and many letters. For such publications, a sulphite paper is used which costs from 7 to 8 cents per pound when purchased in ton lots. The department also prints its own letterheads, using a linen paper which costs about 50 cents per pound wholesale. In a single day there were distributed in Milwaukee 112,000 copies of a milkman's letter, and educational literature for the diphtheria prevention campaign has been published in the department's own printing division.

The Detroit Department of Health has had a division of printing for the past 12 years in which are printed virtually all the forms of the department.

most of its educational material, letters addressed to practicing physicians and other groups interested in the work of the department. The *Weekly Health Review* is also printed.

The Detroit Health Department uses three automatically-fed multigraphs and keeps one hand-fed machine for small work. Two experienced operators are kept busy. The department also has a Set-o-type machine which sets type by use of an ordinary typewriter and just as fast as any typist can write. This machine is used for special reports. The Detroit Epidemiologist has been holding a series of medical clinics at the contagious disease hospital which have been well attended by the medical profession. In fact, the average attendance at these clinics, which are held once a week, has been 230 for the current year. Every week each physician is given a complete report of the previous lecture, which averages from 25 to 35 pages. There are 400 copies prepared each week. This work is all handled on the Set-o-type machine which, as previously stated, writes the story as fast as the ordinary typewriter.

Electroplates are used for all of the fixed forms of the department and the forms are printed on the automatic multigraphs. There is also a mailing list of all physicians in the city which is adjusted to a fill-in multigraph which gives the appearance of a personal letter to each physician addressed. This is a very effective means of stimulating the interest of the practitioner of medicine, as he feels that he is receiving personal attention.

The department also uses a battery

of Hooven typewriters which are used for many purposes, prominent among which are the letters which are sent to all parents as the child attains the age of 6 months, reminding the parents that it is time to have the child protected against diphtheria. This letter has all the appearance of a personal one, the child's name being entered in the body of the communication in two different places, and yet the whole operation is automatic and electrically controlled.

The Detroit Health Department uses a water-marked grade of sulphite bond paper which costs approximately 11½ cents in white and 13½ cents in colors. This paper can be used for most all purposes including the departmental letterhead which is a big factor in the cost of stationery. The department uses approximately 2 tons of paper per month and the saving to the city is approximately 40 per cent of the cost of printing were it done elsewhere. The great advantage of a printing division in a local health department is the improvement in service which is completely within the control of the department. It is possible to prepare over night for an impending epidemic of influenza or measles, printing the record forms to be used by nurses and other employees, as well as the educational material and instructions directed to the parents and general public. (The editor would appreciate receiving a description of the printing divisions of other health departments.)

White House Conference on Child Health—The Committee on Public Health Organization submitted its report to the Conference on November 20, and among its recommendations pertaining to federal health organization were the consolidation of all major health activities under the administration of the U. S. Public Health Service, and the assignment by this Service of personnel to other federal departments.

It was recommended that Congress grant additional authority and appropriations to the Service to broaden its general public health program, especially in the field of child health, and to grant funds and personnel for the development of local health departments.

With regard to state health organization, the committee recommended larger appropriations in the various states and approved the policy of federal aid to stimulate local responsibility.

With respect to city health organization, the committee recommended that there should be provided for every local area (whether city, county or combined units) the service of a full-time local health organization with a well trained personnel and adequate financial support. The committee feels that the experience of the municipal health departments has demonstrated conclusively that programs for the improvement of the health for the mother and child can successfully be conducted only as part of the general program of a well organized health department.

Coördination and coöperation with the nonofficial agencies, with the health officer as the one person in the community directly responsible for the health of its people, was recommended. It was felt that each particular function in the field of health promotion should be performed by the agency best fitted to perform it.

Health administrators recognize the importance of medical service to the health program and therefore commend efforts on the part of organized medicine to improve the quality of medical service and increase its availability. It is further recognized that certain parts of the health program should be further developed by increasing the preventive work of private physicians and dentists.

Health organizations should appreciate the importance of engaging only competent and trained persons and of establishing conditions of employment

which will attract and retain persons of ability. Facilities for instruction should be suited to the needs of the modern public health program. Both the federal and the state health authorities should definitely accept the responsibility for rendering expert consultation service to local governments and for assisting them in expanding their health organization and in improving public health practice. Medical schools should be encouraged to make more adequate provision for teaching preventive medicine and medical practitioners should be encouraged to practice modern curative and preventive medicine in their respective communities.

Health Demonstration in Rutherford County—A report has been prepared covering the period of the Commonwealth Fund Child Health Demonstration in Rutherford County, Tenn., from January, 1924, through December, 1928. The personnel during the 5-year period included a director, a pediatrician, a director of nursing service, 5 white and 1 colored nurses, a director of school health education, and 2 sanitary inspectors. In 1920 there were 33,059 people living in Rutherford County of which Murfreesboro with 8,000 population is the county seat.

At the outstart, there were 3 accepted principles which guided the demonstration: (1) that the rural public health program must be generalized and balanced, (2) that local official status is essential, (3) that the community should be encouraged to provide the greater part of the financial support. The program was planned so that at the end of a 5-year period there would remain in the county a rural health department supported by a locally subscribed budget approximating \$30,000.

In January, 1924, at the very beginning of the demonstration, the director was made Health Officer of Rutherford

County and of Murfreesboro, thus tying the demonstration and the local health organization together. Prior to that time there had been a part-time county health officer who received \$700 a year and a part-time city health officer at \$300 per year. There was no hospital in the county.

The examination of school children was selected as one of the first steps of the program as it immediately brought the health organization into contact with a large number of parents and presented an admirable opportunity to spread health educational propaganda which was so essential to the main objective of the demonstration, that is, creating a local interest and responsibility for the maintenance of organized health service. By 1925 it was possible to set up a new school examination program with two principal objectives—health education and the correction of defects. The blue ribbon plan, which had been used successfully in other child health demonstrations, was employed to stimulate competition and interest on the part of the child and parent. The nursing service was gradually extended. Child health conferences were held, including infant and preschool services, and finally prenatal work was undertaken. At the same time there was an improvement in the sanitary index of the county and a milk control system was established.

By 1929 the county was appropriating \$.03 on each \$100 of assessed valuation which, by the end of the demonstration, had been increased to \$.10, giving a yield of \$22,500 per annum which, added to the appropriations of the city of Murfreesboro, the subscription of the local Red Cross chapter and the funds of the state health department, made a total of \$32,236 or about \$.98 per capita. This sum was available for the continuation of the program at the time the demonstration came to a close.

Prior to the demonstration, the *Appraisal Form* gave the county a score of 110 points out of the possible 1,000, while in 1928 the score had increased to 814 points. A modern 50-bed hospital was built and equipped by the Commonwealth Fund in 1927, and operated with local support.

The broad community health service visualized in 1924 was an actuality in 1928, there being employed from local funds a health officer, 2 sanitary officers, a director of nursing, and 5 staff nurses, 2 clerks, laboratory service, and the expenses incidental to quarantines, transportation, supplies, and equipment.

The State Health Commissioner, Dr. E. L. Bishop, states that success has, in large measure, been attained and provided by the influence of the demonstration on the public health program on the state as a whole and by its stimulus to similar methods of approach in the fields of both technical and administrative methods.—Harry S. Mustard, *Cross-Sections of Rural Health Progress*, The Commonwealth Fund, 1930.

Health Demonstration in Marion County—Comparison is afforded of accomplishment during the 5-year period

1925–1929, during which the Commonwealth Fund maintained a demonstration in Marion County, Ore., with the 5-year period 1920–1924 preceding the institution of such demonstration.

The infant mortality rate of Marion County has been reduced by 22 per cent in contrast to a 13 per cent reduction for the state of Oregon and a 10 per cent reduction for the United States Registration Area. The neonatal mortality has been reduced 24 per cent by the county compared with 13 per cent for the State of Oregon and 6 per cent for the United States Registration Area.

The reduction in the maternal death rate has been 51 per cent for the County, having dropped from 7.3 to 3.6 per 1,000 births. At the same time the mortality rate for the State of Oregon was reduced 17 per cent and there was a reduction of 6 per cent in the United States Registration Area.

Public health work in Marion County in 1924 scored only 202 points out of a possible 1,000 allotted by the *Appraisal Form*. By 1929 the score had increased to 819 points.—E. F. Warner and Geddes Smith, *Child of the Covered Wagon*, Commonwealth Fund, 1930.

LABORATORY

C. C. YOUNG, D. P. H.

AN APPARATUS FOR ROTATING SERUM-ANTIGEN MIXTURES IN THE KLINE TEST FOR SYPHILIS

PHILIP L. VARNEY

Washington University School of Medicine, St. Louis, Mo.

KLINE and Young^{1,2} have described and perfected a micromethod for the diagnosis of syphilis, in which 0.05 c.c. of the serum to be tested is placed in the center of a paraffined ring on a

microscopic slide, a drop of antigen³ added and the reagents thoroughly mixed by rotating the slide. The diagnosis is made with the aid of a microscope. While reliable and sensitive, the

Kline test has the disadvantage of requiring a 4-minute hand rotation of each specimen, necessitating the expenditure of an undue amount of time and labor when many specimens are tested. No apparatus designed to perform this operation has been described.

In an endeavor to relieve the laboratory worker of the necessity for hand rotation, an apparatus which successfully performs this operation has been designed, and is described below. The rotary shaker may be connected to a timing clock possessing electrical make and break connections so that the specimens are automatically rotated for exactly 4 minutes. During this interval, the next series of tests can be set up, or the series just removed from the machine can be read. As a result of the uniform speed and diameter of rotation of all specimens tested, a uniformity of results may be obtained which is difficult to duplicate by hand methods.

The apparatus (Figure I) consists of an electric motor (J), which operates a

standardized speed reducing mechanism (I), causing the slotted head (II), to rotate at a speed of exactly 120 r.p.m., thus producing a corresponding rotary motion of the rotary head (ABC) about the ball bearing guides (E, E'). The rotary head is so constructed as to hold rigidly the 2" x 3" slides commonly used in the test, 6 of which can be rotated at one time.

The base of the rotary head, shown in Figure I (C), is constructed of a well seasoned, stained and varnished oak board, measuring $1\frac{1}{4}$ " x $5\frac{3}{8}$ " x $7\frac{1}{16}$ ". A thoroughly dried board is essential. A rectangle of the above dimensions is first accurately marked out on a larger board, then (Figure II) centering lines are drawn through each of the four corners. Having thus determined the exact center of the board a circle of 3"-radius is scribed on its surface. All markings must be very accurately made. Using a machine drill, a hole $\frac{3}{16}$ " in diameter is bored through the center of the board. Similarly, holes 1" in di-

FIGURE I.—Side view of the rotary machine showing the details of its construction. A. Slide holder. R. Brass base. C. Oak base. DD'. Bearing guides. EE'. Combination radial and thrust ball bearings. F. Connecting rods.

G. Drive pinion. H. Driving head. I. Speed reducer. J. Electric motor. K. Oak support for speed reducer. L. Drive belt. M. Platform. N. Screw holes for side board. P. Oak base.

ameter are bored through the wood at each of the intersecting points of the circular and diagonal marks.

A sheet of hard rolled brass (B), $\frac{3}{32}$ ", of the same length and breadth as (C), is next placed in accurate juxtaposition to the latter, and fastened by means of flat headed machine screws (Figures I and II) and the ends filed off smooth with the surface of the brass sheet. The outlines of the holes through (C) are next scratched on the under surface of the brass sheet, which is then temporarily removed from the wooden base. Four brass bearing holders (D) each $\frac{1}{4}$ " in length, and accurately machined to an internal diameter just sufficient to hold the ball bearings rigidly (E), are next exactly centered over the marks and soldered to the under surface of the brass platform. These holders must be accurately turned and cut in the lathe so that when soldered in position, their axes are at exactly 90° to the plane of the brass sheet.

The brass sheet is refastened to the wooden base, and through it is bored a $\frac{3}{16}$ " hole opposite the center hole in (C), into which is inserted a steel pinion (G), $\frac{3}{16}$ " in diameter and $1\frac{1}{16}$ " in length. This pinion, which extends through the wooden base, is soldered into position, or if desired the end may be threaded and screwed into position.

Brass guides (A), the length of which corresponds to the width of the platform (Figures I and II), are next soldered to the platform. The two outer guides consist of $\frac{1}{4}$ " square brass rod, the inner sides of which are channeled to a depth and width of $\frac{1}{16}$ ". The two inner guides consist of $\frac{1}{4}$ " brass bar $\frac{1}{2}$ " wide, channeled on both sides similarly to the two outer guides. These are carefully soldered into position as shown in the illustrations. Many 2" x 3" slides are slightly wider than 2", but should the particular lot in use be ex-

actly 2" wide or less, the distance between the guides should be slightly decreased. The outer ends of the slide guides should be widened by filing (Figure II), to facilitate placing the slides in position.

FIGURE II—Construction details of the rotary head and slide holders

The slides are inserted in the guides to a depth of $2\frac{1}{2}$ " only, leaving $\frac{1}{2}$ " of the glass protruding for use as a handle in removing the slide. The depth to which the slides are inserted is governed by means of sections of brass bar of the same dimensions and channeled similarly to the two main inner guides, each $1\frac{15}{16}$ " in length, which are soldered to the base (Figure II).

Rectangular pieces of spring brass, 0.01" thick, 1" wide and 2" long, soldered in the center of each slide guide and bent upward so that they press against the bottom of the glass, effectually prevent the slides from being thrown out when the rotary head is in motion.

Nice style R combination radial and thrust ball bearings are used for carry-

ing the load of the radial head. These bearings* have a $\frac{3}{16}$ " shaft opening and an outer diameter of $1\frac{1}{16}$ ". If desired, the four upper ball bearings may be soldered into position or fastened into the bearing guides by screws.

The rotary head is connected to the lower platform (M) by four connecting rods (Figure I(F)), each ground to fit firmly into the ball bearings, and accurately bent so that the ends are parallel. These rods measure exactly $\frac{1}{2}$ " from center to center.

The lower platform (M) is constructed of well seasoned $\frac{3}{4}$ " oak lumber 8" wide and approximately 10" long, in the center of which is an opening 2" wide and $2\frac{1}{2}$ " long, to accommodate the head of the driving mechanism (H). With a machine drill, holes sufficiently large to hold the ball bearing guides tightly (D') are accurately bored in the wood to a depth of $\frac{1}{4}$ " in positions exactly corresponding to those made in (C).

The brass bearing guides (D') are machined to hold the ball bearings (E'), somewhat less tightly than those in the rotary head, so that they may be easily inserted or removed, permitting removal of the entire rotary head. The bearings must not fit loosely, or trouble will result.

Holes through which are placed wood screws for fastening the platform to the side-boards of the apparatus should be bored in the end and sides of the platform (M) (Figure I).

The base (P) of the apparatus is constructed of $1\frac{1}{2}$ " oak approximately 13" long and $6\frac{1}{2}$ " wide for a distance of $7\frac{3}{4}$ ". For the remaining length, the base is $\frac{3}{4}$ " wider on each side, the thickness of the side-boards used to enclose the speed reducing mechanism. These side-boards, measuring $5\frac{1}{2}$ " in width and $7\frac{3}{4}$ " long are fastened to the

base and end by means of screws at the points (N). A 2" oak block (K), $6\frac{1}{2}$ " wide and $5\frac{1}{2}$ " high is glued to the narrow end of the base, and securely bolted in position with 2 4" lag bolts, as indicated. Before this block is fastened to the base, it is drilled to accommodate the lag bolts used to support the speed reducer (I). The location of these holes must be carefully determined by trial, so that when it is bolted in position, the center of the speed reducer is exactly centered between the 4 ball bearings (E'), and in the center of the 2 x $2\frac{1}{2}$ " opening cut through the platform (M).

The speed reducer (I) is filled with soft graphite cup grease, or transmission grease, and then bolted in position with 2" lag bolts. This piece of apparatus is the standardized speed reducer BU-10 made by the Boston Gear Works, and has a speed reducing ratio of 1 to 10. As supplied by the manufacturers, the lower end of the shaft is $1\frac{7}{8}$ " long, and should be cut off to reduce the space needed for the apparatus.

The upper shaft is cut to a length of $1\frac{3}{16}$ ", and a specially made cast iron or brass driving head $1\frac{5}{8}$ " in diameter and 1" thick (Figure I(H)) is fastened on by means of a pointed screw fitting into a depression in the shaft. The driving pinion (G) fits loosely into a slot $\frac{1}{4}$ " wide and $\frac{1}{4}$ " deep, cut entirely across the face of the driving head.

If comparable results with the Kline test are to be obtained by technicians in various parts of the country, conditions such as the time and speed of rotation, and the diameter of the swing of the specimens must be accurately controlled, since preliminary experiments would seem to indicate differences in results obtained by variations of these factors. An arbitrary rotation speed of the specimens of exactly 120 r.p.m. has been selected by the writer, the diameter of the swing being 1". To ob-

* Catalogue No. R-501, Boston Gear Works, Inc., Norfolk Downs, Mass.

tain this speed, it is necessary to determine accurately with the aid of a revolution counter the speed of the particular motor used rather than to trust in the accuracy of the indicated r.p.m. stamped on it. Knowing the speed of the motor, the speed reducer ratio and the diameter of the drive wheel of the speed reducing mechanism, the diameter of the drive pulley of the motor can be readily calculated. The electric motor, which should be not less than $\frac{1}{30}$ H.P., should be of the low speed type, of approximately 1,750 r.p.m. With this, and a speed reducer pulley diameter of 3", a motor pulley with a diameter of 2" should be used to obtain the proper speed of the rotary head.

The motor is fastened to the base by means of lag bolts, and may be connected to the speed reducing mechanism by means of a leather or piano wire spring belt (L). The latter type of belt, while slightly more noisy than leather, does not tend to slip so readily under the light tension which should be used.

The electric connections to the apparatus consist of a standard 110 v. toggle switch and electric cord attached to the motor base. Should it prove desirable automatically to control the 4-minute period of rotation, one of the wires lead-

ing to the wall plug should be cut, and the ends connected to two binding posts screwed into the base of the apparatus. By attaching an electric timing clock in series with these posts, the period of rotation of the rotary head may be easily regulated, relieving the technician of the bother and responsibility of accurately carrying out this step.

SUMMARY

An electrically driven device is described, which mechanically mixes by rotation the serum-antigen mixtures used in the Kline test for syphilis, and which will hold as many as six 2" x 3" slides at one time. The rotary speed of the apparatus has been arbitrarily set at 120 r.p.m., through an arc of $\frac{1}{2}$ " radius. The apparatus may be connected to an electric timing clock, thus relieving the technician of the necessity for timing the period of rotation, resulting in a greater uniformity of results and a saving in the time necessary to perform the tests.

VITAL STATISTICS

LOUIS I. DUBLIN, PH. D.

Vital Statistics for England, 1929—The Registrar General's annual *Statistical Review of England and Wales* gives a population estimate of 39,607,000 for England and Wales, an increase of 0.32 per cent since 1928.

There were 313,316 marriages solemnized during the year, representing a rate of 15.8 persons married per 1,000 persons living. This number and rate are the highest recorded since 1921. The number of marriages celebrated by religious ceremony has decreased from 762 per 1,000 marriages in 1924 to 743 in 1929. Civil marriages have increased from 238 per 1,000 marriages in 1924 to 257 last year. A large number of marriages occurred in the third quarter of the year, the number recorded in the July-September quarter being almost double that recorded from January to March.

There were 643,673 births registered in 1929, equivalent to a rate of 16.3 per 1,000 population, which represents a decrease of 16,594 births or a fall of 0.4 in the rate. There were 29,307 illegitimate births, 395 less than in 1928. The proportion of male to 1,000 female births was 1,043, a figure very close to the proportion in recent years and pre-war years. The maximum was 1,060 in 1919.

The number of parliamentary electors on the register was 25,095,793, of whom 11,866,794 were males and 13,228,999 females. This is the first register in which the number of females has exceeded the number of males. There has been an increase of 5.7 per cent in the number of male voters since the previous register, and an increase of

53.1 per cent in the number of female voters.—*Brit. M. J.*, 2: 660 (Oct. 18), 1930.

Infant Mortality in Southern States—A study of infant mortality in 8 representative southern states showed a higher rate there from 1924 to 1928 than in other states of the Union. Of the 44 states in the birth registration area in 1928, ranked according to infant mortality, the relative positions of the southern states studied ranged from Florida, which stood 23d, to South Carolina, 43d. The average infant mortality rate for the birth registration area for 1928 was 67.7; Florida with a rate of 67.2 was the only southern state that was better than the average.

A study of urban infant mortality was more striking. Among 719 United States cities, with an average rate of 68.3, the urban mortality of the southern states ranged from 65 for Florida cities to 117 for South Carolina cities.

The relative positions of these states have changed little in the 5-year period, 1924-1928. The average annual decline in infant mortality in the birth registration area during this period was 0.4. The four southern states which reported for the full 5 years showed average annual declines from 0.64 for North Carolina to 7.72 for Florida.

A further comparative study of 4 typical cities, New York, Cleveland, St. Louis and Los Angeles, with typical southern cities showed a striking contrast. The average infant mortality over a period of 13 years was 75 for New York, 80 for Cleveland, 72.5 for St. Louis and 68.8 for Los Angeles.

These rates compare with 88.6 for Lynchburg, 89.2 for Jacksonville, 91.6 for New Orleans, 99 for Mobile, 107 for Richmond and 113 for Atlanta for the 13-year period.

Infant mortality in southern states is not only higher than in other group sections of the United States but is really higher than it should be when all conditions influencing it are considered. An important factor in the high infant mortality in southern states is the large industrial population made up chiefly of persons of low intelligence and of very poor financial status. The problem is largely one of improving conditions among this industrial population.

An effort toward improving conditions has been made in Durham, N. C., where well baby clinics were established in 1920. In this city of about 45,000 people, there are now 5 clinics, 3 for white and 2 for colored. Their chief aim is to teach mothers the intelligent, watchful care of their infants. Visiting nurses supervise and teach the mothers in their own homes. In 1928, there was a clinic attendance of 3,380, and the mortality was 56.6 for white and 119.2 for colored infants.—B. W. Brooks, *A Study of Infant Mortality in the Southern States*, *South. M. J.*, 23: 869-873 (Oct.), 1930.

Public Health in a Chinese County
—At least one rural county of disease-ridden China is to have modern doctors and nurses and a real health department. The 400,000 inhabitants will be given a chance for healthier and longer lives.

A rural health experiment is to take place in the county of Ting Hsien, which is in the interior of China. The conditions under which the experiment will be carried out will be hard because of the many difficulties encountered, one of which is the political unrest.

There is at present not one physician of the modern scientific school. The

native doctors think disease is caused by heat and wind; sanitation is unknown. Eighty thousand people live in the county's one city, the rest in squalid villages. About 30 out of every 1,000 die each year. The life expectation is only about 35 years.

The health demonstration has begun by educating the natives to come for medical examination, advice and treatment. Vital statistics are being collected and native nurses, midwives and physicians are being trained in modern scientific methods. The Milbank Memorial Fund has given \$50,000 to aid the work. The League of Nations has announced that it will support and cooperate in attempts to modernize China's health service.—*Science*, 72: 14 (Oct. 17), 1930.

Maternal Mortality in the Registration Area: 1929—The Department of Commerce has announced that for the birth registration area the mortality from puerperal causes (7.0 per 1,000 live births) in 1929 was only five-tenths higher than the rate (6.5) for 1927. Puerperal septicemia was affected even less, the rate for 1927 having been 2.5, as compared with 2.6 in 1929, and the rate for "other puerperal causes" was lowered to 0.3 in 1929. These maternal rates were based on the number of deaths among women 15 to 45 years of age per 1,000 live births.

Confining the discussion to only three groups, namely, "all puerperal causes," "puerperal septicemia," and "other puerperal causes," it was found that of the 46 states for which data were available for 1929, South Carolina had the highest mortality rate (11.4), with Alabama and Louisiana next in order (each 9.9), Florida (9.5) and Georgia (9.3). It must be borne in mind, however, that all the states with excessively high rates have large proportions of colored popu-

lations. Singularly, the states with high rates from "puerperal septicemia" are Montana (4.2), Colorado (4.0), New Mexico (3.9), and Arizona (3.8), all with vast rural areas sparsely settled, where hospital facilities and skilled medical care are difficult to procure.

"Accidents of pregnancy" had a rate of only 0.7 for the entire registration area, "puerperal hemorrhage and other accidents of labor," a rate of 1.6, and "puerperal albuminuria and convulsions," 1.8, while the rates in the states for the three causes, respectively, were highest for Vermont (1.3), Delaware (3.0), and South Carolina (4.7). Heretofore the total deaths from these three causes have been under "other puerperal causes."

Of the cities of 100,000 population in 1920, the highest rate for puerperal causes was for Memphis (16.0), followed by Nashville (14.7), and Birmingham (14.4). These three cities have large colored populations. For "accidents of pregnancy" and "puerperal hemorrhage and other accidents of labor," Memphis again takes the lead, with respective rates of 2.3 and 4.3 per 1,000 live births, while for "puerperal albuminuria and convulsions," New Orleans has the highest rate (4.4). The city with the highest rate for "puerperal septicemia" is Nashville (9.0), followed by Memphis (6.1) and Akron and Birmingham (each 5.7).

Among cities which reached 100,000 population at the census of 1930 the highest rate (14.1) for all puerperal causes is for Jacksonville, Fla., followed by Peoria (12.5); Chattanooga (11.9); Evansville (11.8); Knoxville (11.7); Fort Wayne (11.0); and Tulsa (10.8).—U. S. Department of Commerce. Bureau of the Census.

London's Lowest Birth Rate—The lowest birth rate ever recorded in London is announced for the year 1929.

Births in that year numbered 70,089, or 15.8 per 1,000 population against 16.2 in 1928. The number was actually fewer by 887 than in 1918, when the influence of the Great War was at its height. It is estimated that the population of the official "County of London" has decreased from 5,524,000, at the time of the last census in 1921, by 94,000 to 4,430,000 in the middle of 1929. Deaths in the civil population during the year under review numbered 62,889, or 14.2 per 1,000, against 12.1 of the previous year. This increase was due to the influenza epidemic, associated with an unusually rigorous winter, and in addition to the prevalence of whooping cough. Fatal street accidents increased from 747 in 1928 to 814. The report states that there are about 30,000 basement dwellings in London, housing about 100,000 persons, which are not fit for human habitation. It will be noted that the fall in the population of the "County of London" amounting to 2,263 is not due to excess of deaths over births. It is largely due to migration to the outlying parts of "greater London," which still continues to grow.—*J. A. M. A.*, 95: 1515 (Nov. 15), 1930.

Mortality Experience of the First Nine Months of 1930—Never before have such satisfactory health conditions prevailed in the United States and Canada as during the first 9 months of 1930. The mortality record of approximately 19,000,000 persons, the industrial policy holders of the Metropolitan Life Insurance Company, indicates this clearly. This group constitutes about one-seventh of the population of the two countries, and in the past its death rate has proved to be an accurate index of health conditions in the entire population.

The death rate during 1930, to date, has been low in all parts of the United States, as well as in Canada, where approximately $1\frac{1}{4}$ million of the Metro-

politan industrial policy holders live. In the United States, the colored as well as the white population has enjoyed extremely low mortality rates. The cumulative death rate of 8.0 per 1,000 for the whites in both countries is well below the previous minimum of 8.2 recorded in both 1927 and 1921. For the colored, the death rate for the January–September period was 14.6 per 1,000, which is the lowest since 1922. In neither the United States nor Canada has there been widespread epidemic prevalence of any disease so far this year.

Nineteen thirty, moreover, bids fair to be a year of best records, not only in the low mortality rate for all causes combined, but for several diseases which are of major importance—either numerically or in point of public health interest. The outstanding examples are tuberculosis, diphtheria, diarrheal complaints and puerperal conditions. The typhoid fever death rate, also, is running lower than ever before.

The tuberculosis death rate for the January–September period was 82.9 per 100,000 as compared with 89.8 for the same period of 1929. This marks a reduction of 7.7 per cent in a single year. For white policy holders, the tuberculosis death rate now stands at the unprecedentedly low figure of 64.0 per 100,000.

The cumulative death rate for diphtheria during the January–September period was only 5.8 per 100,000 as compared with 8.3 last year—a drop of 30 per cent. Diphtheria in a few years should become an almost negligible item in our mortality statistics. Measles, scarlet fever and whooping cough are also registering lower death rates than for several years past.

The death rate for puerperal diseases has been declining almost continuously

since 1920. The improvement during 1930 has been especially marked, and has been even greater among the insured colored women than among white women. The influenza death rate for the first 9 months of 1930 (15.6 per 100,000) is less than one-third the rate which prevailed during the like period of last year, and the drop for pneumonia has amounted to 17.4 per cent. Important as are the improvements with respect to all other diseases, the declines for these two have been the chief factors in the large drop in the general death rate, in 1930, as compared with 1929.

The death rates for heart disease and Bright's disease are also running well below the figures recorded for the like period of 1929. From the very beginning of the year, the cancer death rate has shown a slight improvement as compared with 1929. There is a fair prospect that, for the first time in 5 years, the year 1930 will mark a break in the persistent year-to-year rise in mortality from cancer. The cumulative death rate for diabetes is a little lower than that for the first 9 months of 1929, but the favorable margin is smaller than that in evidence earlier in the year. There was a marked increase in deaths from diabetes during the third quarter of 1930, and among both white and colored policy holders the death rate was considerably above the third quarter figure for 1929.

Suicides have been considerably more frequent than in 1929. There has been virtually no change in the homicide death rate. Fatal accidents have not been quite as numerous, although the automobile accident mortality rate exceeds slightly that for the corresponding period of 1929.—*Stat. Bull., Met. Life Ins. Co.*, 11: 1–4 (Oct.), 1930.

PUBLIC HEALTH ENGINEERING

ARTHUR P. MILLER, C. E.

The Grab-Net Method, a Process for the Relative Quantitative Examination of Water Fauna—This is an article (in German) describing an apparatus for the collection of littoral fauna, especially designed for collecting hydracarina (mites), without the use of bait. The net is formed of two cones of bolting cloth, like ordinary plankton nets, fitting one into the other. The foremost is 25 cm. in diameter at the mouth, 30 cm. in side length, and tapers to a 2.5 cm. wide opening.

Its forward opening is held by a brass ring and to the apex opening are attached three cords. The second cone has a widest diameter of 12 cm. and is sewn outside the first cone where its width corresponds. It is 35 cm. long and carries a brass ring about 15 cm. from the point where it is attached to the first cone. To this ring are attached the three cords from the apex of the first cone. These are drawn tight so that the opening is triangular.

The frame of the grab-net consists of three brass or wooden rods fixed to the large brass ring in front and bound together below the apex of the second cone, which is closed with a cord attached to the rods at their junction.

For shallow water the grab-net is attached by two of these rods to a pole which is driven into the ground. The net is moved up or down the pole to the required height, and the inlet opening turned in the required direction. In raising the grab-net it is kept horizontal until just below the surface when the mouth is raised slightly. Above the water it is held vertically and dipped several times to half its length under

water to wash the catch to the lower end. The cord closing the apex of the second cone is then opened and the catch emptied into a collecting vessel.

For deep water, instead of the rod, cords are attached to the ends of the frame and tied together so that the grab-net can be raised horizontally. To their junction a long cord with a float is attached. If the frame is of wood a weight is added. The control of the direction of the opening is not generally so important in deep water but can be achieved by a double anchoring of the grab.

The catch is generally easy of examination being free from sludge and plant admixtures. When used for hydracarina, a sufficient number can be collected without use of bait.

The method can also be used for other animals and as the numbers caught depend upon the number present at the place, the time occupied in collection, and the size of the net, the results serve for relative quantitative examination of the population and for the collection of information as to the movements of water animals.—V. Ozolin, *Folia Zoologica et Hydrobiol.*, 1: 279, 1930. From *Summary of Current Literature*, Water Pollution Research Board, England, III, 10 (Oct.), 1930.

The Sewage Treatment Plant of Iserlohn i.W., the First Activated Sludge Plant Worked by Sludge Gas—The sewage plant of the Ruhr Federation at Iserlohn receives the sewage of a population of 19,000. The sewage is generally fresh but receives intermittently loads of septic material

from sewage pits. The Baarbach, into which the effluent flows is small and at times affords no dilution. The original plant consisted of coarse screens, storm water clarification tanks, sand trap and six Emscher tanks. The storm water tanks were planned to prevent overloading and were later retained for the purpose of equalizing the flow to the plant.

In 1927, plans were started for a more complete purification. Contact aerators, for which the gas from the Emscher tanks was used, were inserted in the settling part of the Emscher tanks, but did not achieve sufficient purification, and an activated sludge plant was added. This is the first plant in which the whole power is supplied by its own sludge gas. Purified sewage is used for cooling in the gas engines and when thus heated is used to heat the sludge in the Emscher tanks.

An illustrated description is given of the plant as extended. Oil and grease are removed in the sand trap by dipping baffle walls and in a new aerated tank after the sand trap. The contact aerators are retained in the Emscher tanks to prevent the intermittently septic state of the sewage from damaging the activated sludge process. The aerators, aeration system and cleaning of the tanks are described.

The secondary settling tanks of both this and the activated sludge tank are provided with central inlets which lead the sewage directly to the lower half of the tank. The activated sludge tanks are on the plan of those at Essen-Rellinghausen, with compressed air and stirrers. From the settling tank part of the sludge is returned to the activation tank and part, with the sludge from the contact aerator plant, enters the Emscher tanks. The method of collection and utilization of gas, the power requirements, the precautions taken to avoid any interruption of the process and the

costs of building and operation are discussed.

The plant has been in operation since August, 1929, and though some disturbance of the activated sludge process has been caused by the intermittent septicity of the sewage already referred to, the operation has been otherwise satisfactory.—W. Schmidt, *Tech. Gemeindebl.*, 33: 133, 1930. From *Summary of Current Literature*, Water Pollution Research Board, England, III, 10 (Oct.), 1930.

Current Conceptions of Sewage Disposal—Here are presented a brief review of developments in the practice of sewage disposal and a consideration of the theories and arguments upon which various processes have been based. The author discusses the development of the biological treatment of sewage, the relative efficiency of land treatment, biological filtration, and the activated sludge process, and methods of aeration and stirring.

The efficiency of the biological treatment depends upon: (1) the closeness, frequency and duration of interfacial contact between the biologically active medium and the sewage; (2) adequate available air; and (3) mechanical efficiency. The biological efficiency of the activated sludge process is high but the mechanical efficiency of the various methods is low. It has been found that the "mechanical" systems of activated sludge treatment provide motion and mixing with efficiency and economy, but that the "diffused-air" system gives the highest aeration efficiency. Investigations are being carried out on the combination of the two systems.

The provision of the necessary oxygen with which to speed up the natural process is considered, special mention being made of Kessener's method of aerating a strong slaughter house waste by means of circulating brushes, the pre-aeration

of sewage, and the elimination of quiescent zones in aeration tanks. The enzyme theory of biological purification is discussed and the possibility of reducing the activated sludge processes to stage treatment using different sludges for preliminary and final treatment is considered. The Dorr clarifier and the Pruss sedimentation tank are briefly described and the advantages claimed for them enumerated. Preliminaries to sedimentation are discussed with special reference to devices for the removal of grit from detritus tanks and to automatic screening apparatus.

Modern methods of sludge treatment by filters and of digestion are briefly dealt with. Sludge digestion, which may be two- or one-stage, depends essentially on control of temperature, reaction, sludge proportion and mixing. The design of works and the need for improving existing works esthetically is mentioned. The article is illustrated by photographs and diagrams.—T. P. Francis, *Surveyor*, 77: 549 and 583, 1930. From *Summary of Current Literature*, Water Pollution Research Board, England, III, 10 (Oct.), 1930.

Water Contamination from Pump Packing—This paper, presented at the 50th Annual Convention of the American Water Works Association, St. Louis, deals with the contamination of three two-stage centrifugal pumps and with the remedy. A description is given of the bacteriological tests and observations made on samples of the water taken from the pumps, service main, and distribution system. Coli-aerogenes contamination occurred after the pumps were repacked. Disinfection of the pumps by secondary chlorination failed to correct this condition.

Studies were made of the packing used and of the bacterial quality and residual chlorine content of the water which dripped continually from the

packing glands. The unused packing and tallow expressed from it were free from coli-aerogenes, but samples of water taken from the first and second stage glands were contaminated. E. C. York pointed out that the drippings from the glands did not represent all of the water which was introduced at the water seal, because some of it must necessarily find its way past the inner rings of the packing in an inward direction and hence into the suction chamber of each stage since the pressure at that point is less than that of the applied water. He suggested that the pressure line be abandoned as a source of supply for the water seal, so that all the water drippings from the glands would have to pass from the suction chamber of each stage in an outward direction and so possible contamination of the water leaving the discharge of the pump would be avoided. This suggestion was adopted and proved a successful solution of the problem.

Various observations made from the experiments are enumerated and references to the literature are given.—A. F. Mellen, *Canad. Eng.*, 58: 693, 1930. From *Summary of Current Literature*, Water Pollution Research Board, England, III, 11 (Nov.), 1930.

Operating Experiences with a New Automatic Residual Chlorine Recorder and Controller—Automatic chlorinating equipment has so far been able to compensate for changes in flow, but not for variations in the chlorine demand of the water. A chlorine control equipment should adjust dosage automatically according to flow changes and to chlorine demand and provide a legally acceptable 24-hour record.

A new automatic residual recorder and chlorine controller is described and its fulfilment of these functions discussed. The equipment is simple in design and operation, and works on an

intermittent system wherein a record is made, chlorine dosage adjusted and everything turned off for a period of time before a new cycle is started.

A detailed and an illustrated description of the equipment for each part of the cycle is given. There are four principal parts to each cycle: (1) A suitable source of light provides illumination which, passing first through a standard solution and then through the solution to be tested, enables a photoelectric cell to measure and compare the color of the solutions. This comparison is expressed by an angle on a rheostat. (2) The angular difference is mechanically transferred to contact levers and the electrical connections are transferred to a chart and to the electrical device operating the chlorinator. (3) The recorder device draws a single line when the standard and residual tests are the same, but any difference energises a plus or a minus magnet and causes short lines at right angles to be drawn. The length of these represents both the difference between residual and standard and the amount of adjustment made by the chlorinator. The chlorinator is a standard automatic vacuum type adapted to electrical control. (4) In the last part of the cycle, provision is made for washing out the old solution, refilling the containers and adding orthotolidin to one of them so that color may develop before the opening of the next cycle. The operation of this equipment in practice in two installations is described.

The equipment can also be adapted to

give warning of approaching pollution in a stream by locating the machine up stream and the chlorinator far enough down stream to protect the supply. Experiments are also being made to apply the machine to hydrogen ion control, and it could be used in the regulation of turbidity or natural color.—J. W. Cutler and F. W. Green, *J. Am. W. W. Assn.*, 22: 755, 1930. From *Summary of Current Literature*, Water Pollution Research Board, England, III, 11 (Nov.), 1930.

Treatment of the Waste Waters of Slaughter and Cattle Yards—The waste waters of the slaughter yards at Cologne are treated in a mechanical clarification plant with screens of 10–20 mm. mesh. Blood wastes are collected separately and utilized. The sludge is collected and removed by an endless carrier and is taken over by a contractor, composted, and used as fertilizer. The clarified waste water enters the city sewers.

The author then refers briefly to the effects of more complete treatment processes, filtration, chemical treatment by lime, and by lime with metal salts, biological processes by filtration or digestion, and irrigation, and describes the conditions of situation and disposal facilities for which the different treatments are suitable.—Butzler, *Gesund. Ing.*, 53: 391, 1930. From *Summary of Current Literature*, Water Pollution Research Board, England, III, 11 (Nov.), 1930.

INDUSTRIAL HYGIENE

EMERY R. HAYHURST, M. D., PH. D., AND LEONARD GREENBURG,
M. D., PH. D.

Report of the Committee on Nomenclature in Occupational Disease as Affecting Standard Practices in Workmen's Compensation—An essential factor in the compensation for occupational diseases lies in a definite and acceptable terminology for these diseases. Compensation boards have awarded compensation for cases ranging all the way from such definite occupational diseases as anthrax or lead poisoning to tuberculosis, appendicitis, and influenza, etc. Report No. 61 of the National Industrial Conference Board, 1923, shows the wide range of afflictions compensated as occupational diseases in the various states in the case of 80 awards made, and the much wider range of claims for compensation from miscellaneous diseases.

A perusal of the New York State Court Decisions in which compensations have actually been made from May, 1923, to August, 1929, shows a list of 76 medical afflictions, of which examples are duodenal ulcer, diabetes, hemorrhoids, rheumatism, apoplexy, anxiety psychosis, hysteria from fright (without injury), Basedow's disease, glaucoma, asthma, pulmonary tuberculosis, tuberculous meningitis, etc.

An accompanying chart of state laws shows the attitude toward the compensation of diseases resulting from or aggravated by accidental injury (taken from *Digest of Workmen's Compensation Laws*, 1927, Workmen's Compensation Publicity Bureau, New York City). Some 37 states allow compensation for cases of disease resulting approximately from accidental injury; 5 states, Hawaii,

and the federal departments allow compensation for any injury proximately caused by and arising out of employment, or resulting from the nature thereof, including diseases; California and Connecticut compensate for the aggravation by injury of preëxisting disease; while 2 states, Connecticut and Kentucky, specifically exclude compensation for the aggravation of preëxisting disease. In practically every state the departments of labor, upheld by the courts, have permitted compensation for disease aggravated, accelerated, developed or hastened by accident.

Obviously legislation is far behind the compensation boards and courts, and it is felt that the inability to agree on the definition of occupational diseases and related terms is a chief difficulty. A search of standard textbooks shows also that even the experts do not agree (Weyl, Glibert, Bourgeois, Paillet), nor do various national committees (Italian, Swiss, etc.).

In Great Britain the Committee on Compensation for Industrial Diseases adopted the following criteria for the inclusion or omission of certain diseases in the occupational disease schedule:

1. Is it outside of the category of accident and disease covered by the act?
2. Does it incapacitate for more than a week?
3. Is it so specific to the employment that causation by the employment can be established in individual cases?

The most acceptable definition of occupational diseases from the medical point of view is, "All diseases which occur with unusual frequency in a deter-

mined occupation." Since the medical point of view may differ from the legal point of view, the committee recommends the following definition: "Occupational diseases shall be defined as those disease conditions in which the employment is the proximate cause." The definition requires a corollary to clarify it in the form of an acceptable classification, as follows:

1. Diseases caused by the inhalation of dust from:
 - (a) Mechanical obstruction of air passages
 - (b) Laceration of mucous epithelium
 - (c) Conveyance of soluble toxic material
 - (d) Conveyance of germs in dust
2. Diseases caused by industrial poisons such as:
 - (a) Poisons which act superficially, as irritant or corrosive (chlorine)
 - (b) Blood poisons (as carbon monoxide, or anilin)
 - (c) Poisons with definite internal or specific effect (lead, arsenic)
3. Diseases caused by fumes, gases, and vapors (poisonous and non-poisonous)—phosgene, metal fume, carbon dioxide
4. Diseases caused by extremes of temperature (heat stroke and exhaustion)
5. Diseases caused by harmful bacteria and microorganisms (anthrax)
6. Diseases caused by compressed or rarified atmospheres (caisson disease)
7. Diseases caused by improper lighting (miner's nystagmus)

The important consideration from a medico legal standpoint is to establish the occupation as the proximate cause of the disease suffered by the worker. This relationship should be determined by medical rather than lay opinion. Present abuses will not be remedied where lay referees arbitrate medical questions (case examples cited).

In the specific use of terms, correct spelling becomes essential.

Due to the difficulty which arises in naming a given occupational affliction by naming the agent which caused it or the disease entity which resulted, the committee has taken up some 25 of the

commoner occupational diseases and attempted to define them with certain explanatory notes (these are the afflictions commonly seen in the usual state schedules of occupational diseases).

(This report, made at the Fort Worth Meeting, was referred to a larger committee of the A. P. H. A., which is working in conjunction with the U. S. Bureau of Census.)—Henry H. Kessler, *Chairman*, May R. Mayers, Irene Rantoul, Bernard S. Coleman, Emery R. Hayhurst, and R. R. Sayers. 27 type-written pages, 2 infolded Tables: 1930. E. R. H.

Public Health Aspects of Atmospheric Pollution (a Summary)—One can go for days without food; one may even do without water for a considerable number of hours; but it is a matter of minutes when it comes to the necessity of breathing uncontaminated air with the requisite amount of oxygen. Perhaps the whole problem of the public health aspects of atmospheric pollution is contained within these sentences.

SOURCES OF ATMOSPHERIC POLLUTION

These may be briefly described under general headings as follows:

1. The combustion of fuels
2. Chemical processes producing noxious gases
3. Animal and plant emanations
4. Miscellaneous causes

In general, atmospheric contamination may be caused by the dissemination of dusts or solid particles, gases, or vapors.

EFFECTS ON THE PUBLIC HEALTH

All grades of severity have been observed, from the mildest type of irritation of the upper respiratory tract to well developed acute manifestations, some of which result in death.

Although the greater number of effects have been observed to produce minor changes in the health and effi-

ciency of individuals exposed, the mortality from poisonous gases and injurious dusts has been steadily increasing within recent years.

This fact nevertheless gives an encouraging aspect to the situation, inasmuch as mortality has in the past served as a better stimulus to concerted action than morbidity.

THE REMEDY

It is a fact that men have always paid more attention to food and drink than to the air which they breathe, in spite of the greater importance of oxygen to the body. Perhaps primeval man in his struggles for existence has built up and sent down to us a series of conditioned reflexes, causing us to take more thought for the food and water supply than for our atmospheric environment.

This may be the reason for our accomplishments in the field of the regulation of water, milk, and food supplies. The mechanism through which these changes have been brought about is by education of the public and regulatory legislation. These same means are at our disposal in the solution of the problem of atmospheric pollution. It is my belief, however, that much more can be done by the dissemination of adequate information than through the passage of laws.

The basis for organization of this work now exists within the American Public Health Association. Engineers, sanitarians, and physicians should collaborate in the working out of safety standards applicable to all conditions in which pollution of the atmosphere occurs.

Finally, one need not look far to see that great good has been accomplished in similar fields by various groups, such as commissions on ventilation, milk commissions, and others. Why not, then, a commission on atmospheric pollution?—C. O. Sappington, National

Safety Council, Chicago. Read before the Joint Session of Sanitary Engineering and Industrial Hygiene Sections of the A. P. H. A., Fort Worth, Tex., October 30, 1930. E. R. II.

The Medical Aspects of Atmospheric Pollution—The health of all higher animals is affected in direct proportion to the concentration of a given pollution in the atmosphere they breathe. Among the common gaseous pollutions are carbon monoxide, gasoline, the gases of mechanical refrigeration, and, especially in the Texas field, hydrogen sulphide from the crude oil containing sulphur compounds.

Where natural gas is used for fuel there is not so much pollution by the suspension of solid particles in the air, and consequently the ultra-violet rays are not obstructed as in coal burning districts. As has been shown by Shrader and others, this has a direct effect on the incidence of bacteria in the air, which reaches a peak of contamination when ultra-violet rays are least. In 1926, Meller reported upon the result of 10 years' enforcement of smoke control in Pittsburgh and found that while the smoke solids had been reduced approximately 70 per cent, the total deposits had increased about 40 per cent. Thus one type of pollution was reduced, but another substituted.

From the medical viewpoint pneumoconiosis due to the breathing of carbon particles and other materials in the air, and silicosis from the inhalation of silica, both of which are materially increased in industrial centers, are matters of constantly increasing interest and concern. Air-borne bacteria in dust are considered slight menaces but the condition is different in the case of droplet infections in the air of a room occupied by a tuberculous patient.

It has been noticed that after a windy day, an epidemic of coughs and colds

often develops. These may be due to the irritation of the wind, dust and pollens, with subsequent bacterial infection. Balyeat reports that approximately 3,000,000 people in the United States suffer from hay-fever and asthma, largely due to wind-borne pollen. Such pollens might be greatly reduced by state and municipal legislation regarding the cutting of weeds and grasses. Many states have legislation providing for the destruction of certain weeds detrimental to agriculture, and these pollen-producing obnoxious plants should be similarly legislated against. The pollen content of the air in the Southwest is much greater than in the North and East. Thus a pollen count of from 6,000 to 7,000 or higher is common with us. The problem is also before us about 12 months of the year: The trees early in the spring; the grasses in the spring and summer; the amaranths and the Russian thistle or tumbleweed from July until frost; the ragweed from the early part of August until frost; and the mountain cedar which begins to pollinate early in December and continues through February. The lack of a moderate amount of rain through October and November shows greatly increased counts in pollen plates, particularly for the ragweed.—T. C. Terrell, M.D. The above is an abstract of the paper presented before the Joint Session of the Sections on Sanitary Engineering and Industrial Hygiene Sections of the A. P. H. A. at Fort Worth, Tex., October 30, 1930. E. R. H.

Effect of Noise on Hearing of Industrial Workers—In this study the acuity of hearing of 1,040 workers in 7 factories was studied. In these factories there were found to be different degrees of noise, varying from those which were comparatively quiet to those which were comparatively noisy. As a control group, a number of employees

of the New York State Department of Labor and the New York State Insurance Fund were examined.

The test instrument was a 3-A audiometer supplied by the Bell Telephone Laboratories. In the present study an arbitrary standard of a loss of ten sensation units was selected as the basis for the differentiation of normal from pathological cases. The amount of noise in the workrooms was measured by a 3-A audiometer also. Of 1,040 persons examined, 76 per cent were found to be possessed of normal hearing. Of the 23.7 per cent who were found to have defective hearing, only 14.9 per cent lacked a previous history of some aural condition which might have been a predisposing factor. Of this group (14.9 per cent) the greatest incidence of deafness was found among workers subjected to the greatest amount of noise. Ninety-six out of a total of 367 workers in that group of plants wherein the noise was between 60 and 80 units were found to be suffering from deafness with no other apparent causative reason than the noise in their environment. There is some evidence that the deafness increased in the older age groups.

It is recommended that, wherever possible, tests of hearing should be made on all employees at the beginning of employment followed by periodic re-examinations when the workers are subjected to more than a moderate amount of noise, and that certain types of noise producing machines be isolated.—*Special Bulletin No. 166*, New York State Dept. of Labor, Bureau of Women in Industry, 1930. L. G.

Medical Care for 15,000 Workers and Their Families—A Survey of the Endicott Johnson Workers Medical Service, 1928—The Endicott Johnson Corporation is one of the world's largest manufacturers of shoes and tanners

of leather. Its factories are located in New York State. In 1918 the management extended medical service to all of its employees. In all, 100 professional and lay workers are employed in the medical department taking care of approximately 34,000 patients yearly and costing slightly less than \$900,000.

The present study indicates that 77 per cent of the workers and their dependents made use of this service exclusively for themselves and their families, and that an additional 17 per cent used it in part. The cost per individual in families which actually used the service was \$25.49 per annum.

This medical organization was studied by Dr. Nellis B. Foster, Dr. Ransom S. Hooker and Dr. Michael M. Davis. In a word, the findings of these investigators may be summed up by saying that the service is on a level with that rendered by the private physicians in the communities in which the plants are located. Dr. Foster found the clinical records of internal medicine somewhat scant. Dr. Hooker found a lack of stimulating leadership and a lack of detail in and coördination of records, while Dr. Davis found certain defects, the correction of which is a matter of sound planning and execution. Aside from these minor criticisms, the service has been found highly satisfactory.—The Committee on the Costs of Medical Care—*Publication Number 5*. L. G.

Workmen's Compensation Legislation—Among the bills which were passed on occupational diseases was one in New York, adding to the list of compensable diseases radium poisoning, or disability due to radio-active properties of substances or to roentgen rays, and disability from blisters or abrasions, from bursitis or synovitis, or from dermatitis or dermatosis. Five defeated bills in New York included one which proposed to designate as occupational

diseases any and all disabling diseases and disabling illnesses contracted in any of the employments coming within the act; another, that "the disablement of an employee resulting from an occupational disease arising out of his employment shall be treated as the happening of an accident within the meaning of the law." Another defeated bill proposed to substitute the term "metal chills," as a name for a listed occupational disease, for the term "zinc poisoning or its sequelae." Still another unsuccessful bill proposed to classify as an occupational disease any disabling disease from pathogenic microorganisms, viruses or toxic substances, acquired by coming into contact with them in a pathologic or bacteriologic laboratory while employed.—*A. M. A. Bulletin*, 25, 7: 158-159 (Oct.), 1930. E. R. H.

Silicosis Among Rock Drillers, Blasters and Excavators in New York City, Based on the Study of 280 Examinations—This is a report of a study of silicosis among New York City rock drillers, conducted by the New York Tuberculosis and Health Association and the DeLamar Institute of Public Health of the College of Physicians and Surgeons of Columbia University, under the direction of a Silicosis Committee of the New York Tuberculosis and Health Association.

The dust studies made in conjunction with this research were conducted by the Industrial Hygiene Laboratories of the Metropolitan Life Insurance Company of New York City, the funds for the study being provided by the Altman Foundation. The report consists of 5 parts: (1) the introduction, (2) a study of the clinical aspects of the problem, (3) a study of the dust content of the air in rock drilling and blasting operations, (4) conclusions, and (5) recommendations of the committee.

The clinical aspects of the study were

conducted by Dr. Adelaide Ross Smith of Columbia University. In this portion of the study, 230 men were examined and X-rayed, but 22 cases were discarded, leaving a total of 208 cases for the complete study. Forty-three per cent of the workers were found to be negative; 23 per cent were found to be suffering from ante-primary silicosis; first stage silicosis included 19 per cent; second and third stage silicosis, 15 per cent. With reference to the duration of exposure, it was found that second and third stage silicosis did not begin to occur until a 5-9-year working period and it was at its maximum occurrence in the 20-29-year working period. First stage silicosis occurred in less than 2 years and had a high incidence between 2 and 4 years.

With reference to symptomatology, cough, dyspnea, and pain in the chest were found to be of frequent occurrence among workers suffering from all stages of silicosis. Ten per cent of the total number of workers were found to have heart disease of some type. Blasters, rock drillers and excavators were affected by the disease in frequency and severity in the order named. Second and third stage silicosis occurred four times as frequently among those who had done underground work as among those who had only done open excavation.

The dust studies were performed by J. W. Fehnel, Chemist for the Metropolitan Life Insurance Company. These

studies indicate a free silica content of from zero to 84 per cent; a total silica content of from about 56 per cent to 94 per cent with a total number of dust particles of from 2 million to 17 billion per cu. m. of air. The conclusion that rock drillers in New York City are exposed to a dangerous dust, great in quantity, is apparent.

The committee recommended that remedial measures are urgently needed in this occupation; that efforts must be made immediately to improve the conditions by dust control technic, and that compensation should be granted for disability due to silicosis.—*J. Indust. Hyg.*, XI, 2 (Feb.), 1929. L. G.

Bibliography on Industrial Fatigue and Allied Subjects—This is a supplement to the second edition of the *Report of the Committee for the Study of Industrial Fatigue of the Industrial Hygiene Section*, including material through May, 1930, and consists of a printed bulletin of 11 pages, arranged by authors in alphabetical order with a line or two of abstract material under each citation.

Those interested in the *Bibliography* should address either Dr. Eugene L. Fisk, Chairman of the Committee (Medical Director, Life Extension Institute, 25 W. 43d St., New York, N. Y.), or Dr. Carey P. McCord, Section Secretary (Director, Industrial Conservancy Laboratories, 34 W. 7th St., Cincinnati, O.).

FOOD, DRUGS AND NUTRITION

WALTER S. FRISBIE

Vitamins A and D in Fish Oils—Experiments in the past have shown that fish oils contain varying amounts of vitamins A and D. In view of the importance of these oils in animal feeding and the fact that both the quality and quantity of the oils can be increased, a more thorough study was undertaken by the Bureau of Chemistry and Soils of the U. S. Department of Agriculture in coöperation with the Bureau of Fisheries, of the U. S. Department of Commerce. Commercial oils—salmon, sardine (California pilchard), menhaden, Alaska herring, Maine herring, and tuna—were used and the method of manufacture and origin were known.

In testing for vitamin A, the first tests were carried out on 32 albino rats, divided into 8 groups. Two groups were used as controls; one received the basal diet only and the other received 10 mg. per rat daily of a medicinal cod liver oil of high vitamin A potency. The remaining group received 10 mg. daily of each of the oils to be tested. The oils were diluted with peanut oil so that 0.1 c.c. of oil carried the desired daily dose. Of the oils tested, salmon oil was the only one that falls in the same class with cod liver oil. The groups on tuna and salmon oils survived longer than the control and did not develop severe ophthalmia so rapidly, indicating that these oils contain vitamin A. To obtain a more accurate comparison between cod liver oil and salmon oil, three groups (6 rats each) were fed daily doses of 5 mg. of cod liver oil and 10 and 20 mg. of salmon oil. It was found that salmon oil had one-third the vitamin A potency of

the cod liver oil. Sardine, Alaska herring, and tuna oils were found to be about one-tenth as potent as cod liver oil. Maine herring was about one-half as potent as Alaska herring oil and menhaden oil was found to contain no vitamin A.

In testing for vitamin D, rats 4 weeks old and weighing 60 to 65 gm. were put upon Steenbock Diet 2,965. In 23 to 25 days the oil to be tested was added to the diet and after 10 days the animals were killed and their bones examined for healing of the rachitic metaphysis. If the arbitrary figure of 100 is assigned to the vitamin D value of cod liver oil, the oils tested have the following vitamin D values: tuna, 125; sardine, 100; menhaden, 75; salmon, 50; Alaska herring, 30; and Maine herring, 15.—E. M. Nelson and John Ruel Manning, *J. Indust. & Eng. Chem.*, 22: 1361 (Dec.), 1930.

Observations on a Diatom (Nitzschia Closterium W. Sm.) as a Source of Vitamin A—Although previous experiments have indicated that the oil of Nitzschia Closterium, a marine diatom, is potent in vitamin A, it did not give the color reaction and it was, therefore, decided to repeat the experiments and also get a more quantitative estimate of the activity of this diatom. The oil was studied both biologically and colorimetrically. It was found rich in natural plant pigment, chlorophyll, xanthophyll, carotene, and fucoxanthin and gave a blue color reaction with SbCl_3 . The results of this experiment lead to the suggestion that these diatoms are the ultimate source of vitamin A of the fish-liver oils and that a

similar change. takes place in the cod giving rise to the stores of colorless vitamin A present in the liver oils, and also explains why liver oils of fish may be very pale in color and at the same time very rich in vitamin A.—Bashir Ahmad, *Biochem. J.*, 24: 860, 1930.

Fat Soluble Vitamins. Butterfat: Its Antirachitic Properties and its Artificial Activation—In the past it has been shown that the antirachitic potency of many oils and fats including butterfat can be increased by irradiation. The experiments here recorded concern the conditions necessary to secure maximum activation of butterfat. For the experiments, 50 lb. of June butterfat were used. For the irradiation, an Alpine Sun Lamp was used for the most part but in some of the experiments a Cooper-Hewitt mercury vapor lamp of the B. Y. type was used. The distance of exposure was kept at 18" and in no case was the temperature allowed to exceed 50° F.

Using a film of fat 160 mm. thick, most of the activation by exposure to the ultra-violet radiations of the apparatus occurred in the first 10 minutes of exposure or less. The second 10 minutes caused additional activation, but the effect of the third 10 minutes was questionable. After that, irradiation for a total of 2 hours or more caused no increase. When radiation was continued for a total of 16 hours, the activation originally induced or originally found in the butterfat was totally destroyed. The activating strength of the two types of lamps was found to be approximately equal.

June butterfat was found so low in vitamin D that 5 per cent of the weight of a rickets producing ration or an intake of about 400 mg. per rat daily did not allow normal bone production. It did, however, contain sufficient activatable constituents so that treatment with ultra-violet radiations under suit-

able conditions made an intake of 20 mg. of it per rat daily equivalent in antirachitic potency to 400 mg. of the untreated. A sample of cod liver oil was found about 40 times as potent as the June butterfat. The potency of irradiated butterfat was found stable to storage, and no deleterious effects of judicious irradiation were detected. It is concluded that it is practicable to activate butter by the introduction of irradiated ergosterol.—H. Steenbock and Alice M. Wirick, *J. Dairy Sci.*, 13: 497 (Nov.), 1930.

Meat in Nutrition—I. Preliminary Report on Beef Muscle—Meat, like milk, has been subjected to varied tests to determine its rôle in nutrition. This paper describes the growth, reproduction and lactation performances of three generations of albino rats on a diet in which the main protein constituent was lean muscle beef. Excellent growth and reproduction were secured in rats consuming a meat ration supposedly sufficiently fortified with the necessary vitamins and mineral matter. Cannibalism and failure of the milk supply were frequent occurrences among the rats fed the meat ration, but no difficulties were encountered with the rats fed the control ration. No noticeable results were observed when the meat ration was modified by increasing its yeast salt mixture and protein contents.—P. Mabel Nelson, Margaret H. Irwin, and Louise J. Peet.

II. Some Dietary Factors Influencing Lactation—This experiment was carried through three generations to discover what constituents should be added to the basal meat diet to obtain successful lactation. While the meat ration proved suitable for growth and reproduction, it failed to meet the needs of the mother during lactation. The diet modified by the addition of tikitiki and wheat germ oil, and the control basal diet were least efficient in maintaining

the weight of the mothers during lactation. Mothers on the increased meat diet plus 15 per cent yeast weaned the largest percentage of the young born in the three generations, but in the first and second generations an even larger percentage was reared by the mothers fed the basal diet with the autoclaved yeast addition.—Louise Jenison Peet, P. Mabel Nelson, and Erma A. Smith.

III. Hemoglobin Formation—Since further confirmation of the adequacy of a ration may probably be obtained by a determination of the percentage concentration of the hemoglobin of the rats on the ration, the number of gm. of hemoglobin per 100 c.c. of blood was determined for the young of the rats on the different diets used in the experiments reported in experiment II. Tables are given showing the hemoglobin determinations. The diets which contained an increased percentage of yeast, autoclaved yeast, tikitiki, lemon juice, or wheat germ oil, led to significantly greater hemoglobin formation in the young than the diets containing increased protein.—Louise J. Peet, Erma A. Smith, and P. Mabel Nelson, *J. Nutrition*, 33: 303 (Nov.), 1930.

Does the Nickel Dissolved from the Container During Pasteurization Catalyze the Destruction of the Vitamins of Milk?—Since nickel is used more extensively in industrial machinery than is copper, and since in previous years the work of Hess (*J. Indust. & Eng. Chem.*, 13: 1115, 1921), and Hess and Weinstock (*J. A. M. A.*, 82: 952, 1924) suggested a catalytic destruction of vitamin C in milk by copper, this experiment was undertaken to determine if nickel catalyzes the destruction of vitamins in milk. In the experiments 390 rats and 140 guinea pigs were used. Vitamins A, B, and C were studied and three groups of rats were fed a ration otherwise adequate and supplemented by raw milk, milk

pasteurized in glass, and milk pasteurized in nickel. The nickel content of milk pasteurized in a nickel container was found to be 15 p.p.m. nickel while the same milk pasteurized in a glass vessel contained no nickel.

There was no appreciable destruction of vitamin A by pasteurization in either glass or nickel.

The antineuritic factor of the vitamin B complex was partially destroyed by pasteurization but there was no evidence of a catalysis of the destruction by nickel.

Vitamin C was partially destroyed by pasteurization but it was not shown that nickel increased the destruction.

After studying the rate of development of deficiency diseases, acuteness of symptoms, autopsy findings, and growth curves, it is not indicated that nickel dissolved from the container during pasteurization catalyzes the destruction of vitamins A, B, or C during pasteurization.—Avery D. Pratt, *J. Nutrition*, 3: 141 (Sept.), 1930.

An Unusually Mild Recurring Epidemic Simulating Food Infection—In various localities of the northwest mountainous section of the United States, particularly in certain of the national parks, although never limited to these areas, a mild dysentery-like epidemic has occurred from year to year during the hottest and driest months of the year. In 1929, there was a large number of cases in Yellowstone Park affecting both employees in the park and tourists. The symptoms were practically identical—nausea, vomiting, sharp pain in the abdomen and diarrhea with rapid recovery. It was estimated that at least one-half the employees throughout the park including hotel employees, storekeepers, forest rangers and others were stricken with the illness. Tourists stopping at hotels and those camping were affected. Although the symptoms were those of food poisoning

there was no common item of food. It was learned that a similar illness was prevalent at Livingston, Butte, Missoula, and Hamilton, Mont.

During 1930 there was a recurrence of the outbreak and the author personally saw 38 cases and obtained records of the occurrence and the symptoms of 57 others. There were undoubtedly additional cases in Yellowstone Park during that summer. Blood cultures and throat cultures from those affected yielded no pathogenic organisms. The serums from 6 cases were tested against a number of common food poisoning organisms. In 2 cases agglutinations were obtained with *B. dysenteriae* (Shiga)—one in a dilution of 1: 160 and the other in a dilution of 1: 320. All other serological tests were negative. The water supplies were free from contamination; sewage was properly and carefully disposed of; and the sanitary conditions surrounding the handling of food were beyond criticism. Food supplies for the various hotels and camps were obtained from different sources. The milk used was pasteurized and the meat and other perishable foods were transported to the park in refrigerator motor trucks. In-

vestigation disclosed that the Yellowstone hotels and lodges do not use a manufactured silver polish which might be considered a possible cause of illness. Many people attributed the sickness to the pine pollen. This was disproved.

Comparison of the symptoms with those of botulism, bacillary dysentery and food infections due to the paratyphoid-enteritidis group of bacteria showed that there was no similarity to botulism, some suggestions of bacillary dysentery, but a closer resemblance to paratyphoid-enteritidis infection.

The inability to connect the cases with infected food rather disproves the theory that the paratyphoid-enteritidis group might be the causative agents. The above considerations, especially the definite agglutination of *B. dysenteriae* (Shiga), suggests the possibility that these epidemics are either mild outbreaks of bacillary dysentery, caused probably by an attenuated strain of the Shiga type of organism, or else an unknown organism belonging to the same group. Why the condition does not spread to the large centers of population in the East remains unexplained. —R. R. Spencer, *Pub. Health Rep.*, 45: 2867 (Nov. 21), 1930.

CHILD HYGIENE

RICHARD A. BOLT, M. D., DR. P. H.

THIS section aims to present in general outlines the fundamental factors which condition the health of mothers and children. It will attempt to integrate child hygiene with the social, economic, educational, and public health movements of the times as illustrated by actual field experiences. The relative values of the various phases of the subject will be discussed, and criterions of effectiveness set forth.

It is hoped that every member of the Association, and especially those of the Child Hygiene Section, will take an active interest in the development of these columns and send in current reports of promising work, new features of child hygiene programs, and results of local child health activities. Material and suggestions for the betterment of this section will always be welcomed.

In reopening the Child Hygiene Section it seems desirable to present a statement as to the scope and interrelations of this subject. An outline of a tentative plan for presentation of current material as it may be brought to the attention of the editor from month to month is sketched in this issue. It is planned to record not only the progress of child hygiene as illustrated by outstanding pieces of local work, but also to give coherence to this material by indicating its bearing upon a general community program for maternity and child health.

Child hygiene is an integral part of the public health. It is intimately related to sanitation of the environment on the one hand, and on the other, with even greater force, to personal hygiene of the child applied directly in the home and community. In a somewhat re-

stricted sense child hygiene was formerly considered to cover only the prevention of disease and correction of remediable defects. Within the last decade its meaning has been broadened to include all health activities for the welfare of both mother and child. This is reflected in the newer term, child health, which brings together two strong Anglo-Saxon words conveying the idea of wholeness or fullness of life for the child. It connotes mental and bodily vigor, strength, alertness and buoyancy as well as prevention of disease.

Maternity and child health cannot be separated. The mother is the fostering environment of the child for many months. Madonna and child are the true type of affectionate care. The preservation of this tender relationship is one of the main objectives of child health work. No child hygiene plan can be considered complete unless linked to the protection of maternity.

Child welfare is a term loosely used to cover every phase of social work dealing with the child. The present-day tendency is to apply it to many diverse activities, including health, education, recreation, physical training, mental hygiene, and prohibition of child labor, as well as to the care of dependent, delinquent, and handicapped children.

In this section, child hygiene and child health will be used interchangeably to designate the significant features of public health activities, official, semi-official and voluntary, aimed to protect, promote, and conserve the health of children from the time of conception through adolescence. While it is not possible in actual experience to segment

the child's life, it will be convenient, for purposes of periodic presentation and discussion, to consider the essential elements of child welfare activities under a number of well recognized divisions which more or less overlap or interdigitate. These are as follows:

1. *General Public Health Measures* which have a direct or indirect bearing upon the health of the mother and child, e.g., the control of communicable diseases, the protection of water and milk supplies, and public health nursing.

2. *Maternity Welfare* which provides for adequate prenatal care, skilled obstetrical service, nursing and ample hospital facilities for maternity care.

3. *Infant Hygiene* with community measures for the prevention of early and late infant mortality, and instruction of mothers

in the proper care of their children.

4. *Preschool Child*—Provisions for prevention (including suitable immunization) of diseases and the correction of remediable defects. This is the period of relatively low mortality but high morbidity and damage which may affect seriously the future career of the child. Health habits are most easily inculcated at this time.

5. *School Health* should be assured by thorough physical examination of every school entrant, provision for correction of defects, prevention of communicable diseases, compliance with a hygienic school regimen and development of health education.

6. *Health of the Child in Industry*—Careful supervision of children entering any industrial employment; issuing of working papers only after a thorough physical examination and a determination as to whether the work offered will bring about any injury; prohibition of child labor in dangerous or deleterious occupations.

DECLARATION OF PRINCIPLES EVOLVED FROM THE WHITE HOUSE CONFERENCE ON CHILD HEALTH AND PROTECTION

AT the final meeting of the White House Conference the following summary of principles was adopted as an introduction to the four reports presented by the chairmen of the different sections. It was understood that any corrections or additions deemed necessary by the Procedure Committee would be added later:

"Every American child has the right to the following services in its development and protection:

1. Every child is entitled to be understood and all dealing with him should be based upon the fullest understanding of the child.

2. Every prospective mother should have suitable information, medical supervision during the prenatal period, competent care at confinement. Every mother should have postnatal medical supervision for herself and child.

3. Every child should receive periodical health examinations before and during the school period, including adolescence, by the family physician, or the school or other public physician, and such examination by specialists and such hospital care as its special needs may require.

4. Every child should have regular dental examination and care.

5. Every child should have instruction in the schools in health and in safety from accidents, and every teacher should be trained in health programs.

6. Every child should be protected from communicable diseases to which he might be exposed at home, in school or at play, and protected from impure milk and food.

7. Every child should have proper sleeping rooms, diet, hours of sleep and play, and parents should receive expert information as to the needs of children of various ages as to these questions.

8. Every child should attend a school which has proper seating, lighting, ventilation, and sanitation. For younger children, kindergartens and nursery schools should be provided to supplement home care.

9. The school should be so organized as to discover and develop the special abilities of each child, and should assist in vocational guidance, for children, like men, succeed by the use of their strongest qualities and special interests.

10. Every child should have some form of religious, moral and character training.

11. Every child has a right to a place to play with adequate facilities therefor.

12. With the expanding domain of the community's responsibilities for children, there

should be proper provision for and supervision of recreation and entertainment.

13. Every child should be protected against labor that stunts growth either physical or mental, that limits education, that deprives children of the right of comradeship, of joy and play.

14. Every child who is blind, deaf, crippled, or otherwise handicapped, should be given expert study and corrective treatment where there is the possibility of relief, and appropriate development or training. Children with subnormal or abnormal mental conditions should receive adequate study, protection, training and care.

15. Every waif and orphan in need must be supported.

16. Every child is entitled to the feeling that he has a home. The extension of the services in the community should supplement and not supplant parents.

17. Children who habitually fail to meet normal standards of human behavior should be provided special care under the guidance of the school, the community health or welfare center or other agency for continued supervision or, if necessary, control.

18. Where the child does not have these services, due to inadequate income of the family, then such services must be provided to him by the community. Obviously, the primary necessity in protection and development of children where poverty is an element in the problem is an adequate standard of living and security for the family within such groups.

19. The rural child should have as satisfactory schooling, health protection and welfare facilities as the city child.

20. In order that these minimum protections of the health and welfare of children may be everywhere available, there should be a district, county or community organization for health education and welfare, with full-

time officials, coördinating with a state-wide program which will be responsive to a nation-wide service of general information, statistics and scientific research. This should include:

- (a) Trained, full-time public health officials with public health nurses, sanitary inspectors and laboratory workers
- (b) Available hospital beds
- (c) Full-time public welfare services for the relief and aid of children in special need from poverty or misfortune, for the protection of children from abuse, neglect, exploitation or moral hazard.
- (d) The development of voluntary organizations for children for purposes of instruction, health and recreation through private effort and benefaction. When possible, existing agencies should be coördinated.

"It is the purpose of this conference to establish the standards by which the efficiency of such services may be tested in the community and to develop the creation of such services. These standards are defined in many particulars in the reports of the committees of the conference. The conference recommends that the continuing committee to be appointed by the President from the conference shall study points upon which agreement has not been reached, shall develop further standards, shall encourage the establishment of services for children, and report to the members of the conference through the President."—*Official Report of the White House Conference on Child Health and Protection*, Supplement to the *United States Daily*, V, 228, Nov. 28, 1930.

PUBLIC HEALTH NURSING

EVA F. MACDOUGALL, R. N.*

Public Health Nursing in Syracuse, N. Y.—Public health nurses have been employed in the Syracuse Health Department since 1909. In 1926 all these nurses were transferred to a newly organized bureau of nursing and a generalized educational program was adopted. The city is divided into 31 districts and a nurse assigned to each carries on a generalized program, except for public school nursing and bedside nursing. Her services cover prenatal care, infant and preschool hygiene, communicable diseases, tuberculosis, and parochial school hygiene; nutrition and mental hygiene function in each of these services also.

The Child Hygiene Committee of the Community Chest pays the salaries of the prenatal supervisor and 2 delivery nurses in the Nursing Bureau. These nurses aid in the prenatal clinics, make home visits, and assist in the home deliveries, attended by senior students in the Medical College of Syracuse University. The prenatal supervisor is responsible for the technic and clinical standards of the health department nurses, and instructs new nurses in the maternity service.

The Syracuse Department of Public Instruction employs 23 nurses to serve the city's 41 grammar schools, and 1 nurse to render a limited service to the high schools. These nurses assist the school physician, give first aid, assist in control of communicable diseases, make home visits to pupils, and inspect the

school plants. The nurses' home visits are an essential part of the whole school health program.

The Visiting Nurse Association of Syracuse, another Community Chest agency, does bedside nursing care in the homes to maternity cases, to those ill with communicable and non-communicable diseases, and to acute and chronic cases. The nurses in this organization also teach personal hygiene, sanitation, and the prevention of disease. The organization has an hourly nursing service and a 24-hour emergency maternity service.—Public Health Nursing in Syracuse, *Better Health*, Dept. of Health, Syracuse, N. Y., V, 10: 2 (Oct.), 1930.

Tuberculosis Nursing Yardsticks—In a series of Tuberculosis Institutes held in Indiana in October under the auspices of the Indiana State Tuberculosis Association and the Public Health Nursing Division of the State Board of Health, Violet H. Hodgson, R.N., Assistant Director of the National Organization for Public Health Nursing, gave the public health nurses 9 qualitative yardsticks by which they might measure the efficiency of their tuberculosis work:

1. Are you finding new cases in the early stages?
2. Are you succeeding in getting physical defects corrected?
3. How long does the tuberculous patient remain in the sanatorium?
4. How much does personal and home hygiene improve when the patient remains at home? (The record is the yardstick.)
5. Does the home management improve?
6. Does the ability of members of the family to cooperate improve?

* Please send printed matter or other material relating to public health nursing to Eva F. MacDougall, 6 State House Annex, Indianapolis, Ind.

7. Is the post-sanatorium case rehabilitated in the home?
8. Is your teaching ability improving?
9. How long does the family carry out the mode of living you have taught them?

Public Health Nurses and the Committee on the Costs of Medical Care—Medical societies, health officers, and 320 public health nurses of 15 states and 3 cities outside of these states have been collaborating with The Committee on the Costs of Medical Care in a survey to gather "information regarding the incidence of illness, the expenditures that are made for its prevention and care, the individuals or agencies providing the care, and the distribution of expenditures among families of various income levels."

Families living in cities, towns and rural areas are the types studied. The nurses make house-to-house canvasses of certain families to explain the objectives of the study and get them interested enough to undertake systematic recording of all illnesses and expenditures. To the family who is interested in the study the nurse returns every 2 months to get histories of all illnesses that have occurred since her last visit. During the 12-months period of observation there are 6 interviews (usually representing at least 10 calls) with each family. This calls for a great deal of patience and perseverance on the part of the nurses.

The schedule used in the study is designed to show in detail the history of each illness in a family during a period of 12 months, the type and amount of medical care received, and all financial obligations incurred during that time for medical care. For the purposes of this study, an illness is defined as any disorder which wholly or partially disables an individual for one or more days or for which medical service of any kind is received. Any symptom or disorder for which drugs costing \$.50 or more are purchased is considered an illness.

Nursing, dental and eye care, treatments by osteopaths, chiropractors, and Christian Sci-

ence practitioners, professionally or self-prescribed medication, laboratory work, health examinations and immunizations, and other items are included. Free work by practitioners, hospitals, and clinics, illnesses for which no practitioners are called, and minor ailments are recorded as consistently as costly major operations.

When completed the study will include about 15,000 families.—The Costs of Medical Care: Preliminary Report by Nathan Sinai and Margaret C. Clem, *Miscellaneous Contributions on the Costs of Medical Care*, 2: 3-4 (Nov. 1), 1930.

A Health Officer Describes the Right Kind of Public Health Nurse—Some Don'ts For Her—

1. She may not diagnose or prescribe (not even a cathartic), for only the physician is trained to do these.
2. She may not advise a patient as to who is the best physician to consult about a particular malady, as this function can better be undertaken by the local medical society or the hospitals.
3. She may not choose for the patient among reputable hospitals, for this would tend to make her the source of endorsement for individual hospitals.

Some wonder how the public health nurse can be so important in the control of communicable disease when she cannot diagnose:

There is really no mystery about it. Her training enables her to distinguish the sick from the well; suspicious cases are referred to a physician for diagnosis. Her duty is done when she sounds the alarm upon suspicion. She administers the regulations laid down for her guidance by the state health department or the legislature. All this is done under the direction of the city or county health officer, or in the case of the county nurse working alone, under the direct supervision of the state board of health.

What She Is—

1. The backbone of any public health program worthy of the name
2. Interpreter of the physician to the layman
3. Liaison between headquarters and the

fighting line of control of contagious disease

4. The eyes and ears, hands and feet of the health officer

5. Purveyor to the people of the results of research

6. Health guardian of the school child, the runabout and the infant

7. The messenger of hope to the tuberculous

8. The personification of the statesman's

first responsibility, the care of the public health

9. Her whole reason for being is that she is an educator. Everything she does, though it may seem like service, is done with the educational motive.—

W. W. Bauer, "Knocking At Your Door," *Hygeia*, Dec., 1930, pp. 1145-1147.

EDUCATION AND PUBLICITY

EVART G. ROUTZAHN*

Readers Are So Queer—If only words meant the same thing to readers as they do to writers how much simpler our publicity task would be. A surprised and aggrieved writer wonders why his good advice went wrong.

Something seems to be definitely wrong with the three editorials recently published in the columns of this periodical, on patent medicines. No less than three correspondents have written this Bureau for advice as to *what patent medicine to buy*, under the circumstances of their illness. In each case the writer stated that he had tried certain nostrums without result. Attention was called to this mistaken conception of patent medicines, by a previous note in this column, in the October number. It must be repeated that money spent on any patent medicine is wasted. See your family physician and take his advice. He is a trained man—the patent medicine manufacturer has only one interest in life—his own pocketbook.—*Jamaica Public Health Bulletin*, Kingston, Nov., 1930.

What Kind of Meetings—And where do meetings fit into the plans for any public health project, little or big? To help think this out the classification given below is being tested in the Course in Publicity, New York School of Social Work:

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

1. Administrative: Staff—board—committees—membership—annual—clubs and classes; Special jobs and emergencies (legislative—epidemic—unemployment—and so on); Inter-agency.

2. Public emergencies: Legislation—epidemic—unemployment—financial campaigns.

3. Educational: Health education—discussion groups about case work—lecture courses on social problems.

4. Ready-made audiences: Clubs, societies, churches, radio, etc., which can be utilized—see Directory of Organizations in A B C of Exhibit Planning (pages 208-209).

(May be used for public emergencies—education—financial campaigns.)

(May be utilized partly through direct representation—and partly through the sending of announcements, letters, speakers' notes, program plans, plays, etc.)

(May include brief announcements or statements, discussion periods, dramatic or stunt features, single talks, lectures, groups of papers or addresses, demonstrations of work, etc.)

5. Professional: Conferences of health and social workers—national—state—local—inter-city. Discussion groups. Institutes.

A Blueprint for Constructing the Annual Report—A model narrative report for the consideration of nurses and nursing committees to serve as a guide for each nurse when she comes to appraise her work for the month is outlined in *The Red Cross Courier*, Washington, D. C., Nov. 15, 1930.

The editor says:

This rather full outline is meant to be helpful. The new Contract Bridge player keeps his "Work," "Elsworth" or "Whitehead" on his knees for constant reference as he makes each play and bid until his bidding and playing become automatically efficient. Why not use this outline in the same way? Surely there is as much incentive to a public health nurse to write a live, valuable narrative statement of her service as there is incentive to a card player to play a corking, clever game of Contract Bridge.

Here are two sample paragraphs from the outline:

The Daily Work—Human interest stories, short, crisp, alive, uncovered either in work with a single patient, a family or in some group activity; i.e., Home Hygiene class or mothers' club.

Publicity—The fact that the publicity program for the year is being planned and completed; chief objective of the plan, general scheme: editorial in a newspaper; special news item; talk before a ladies' aid meeting; subject; how received, how many present. Report on a window exhibit, subject and purpose, occasion for, success, etc. Roll Call publicity work; work in behalf of Red Cross; response of the public to these various stimuli.

Board Members at Conventions—

Board members are getting their innings at state nursing meetings—and nursing service will be the better for it. At state meetings of nursing groups in Iowa, Pennsylvania, Connecticut, and New York, sessions of great interest were held for board and committee members, as reported in *Public Health Nurse*, 370 7th Ave., New York, N. Y., Dec., 1930. 35 cents.

In Iowa a county superintendent of schools urged "the necessity of publicity in public health procedures."

In Connecticut each one at a luncheon sought to gather information "by sitting next to some one she had never seen before." Also "the advantages of making charts of conditions in associations were brought forward." Here too "a careful review of the *Board Members' Manual* was given by the Education Committee."

One New York session was a luncheon for members of hospital boards, visiting

nurse association boards, nursing school committees, and Red Cross committees. One New York session discussed "Professional Reading," and "how the work of reading and reporting on health reports, magazine articles, etc., might be allotted to board members and brought to board meetings."

In Pennsylvania one speaker outlined how to use the *Board Members' Manual* and another told "how to make a board meeting interesting."

Would not most national and state health meetings get out more board and committee members through the added attraction of well planned sessions taking up health activities from the standpoint of the volunteer worker?

Some Comments on Teaching Through Exhibits—This department has asked some of the members of the American Public Health Association who attended the International Hygiene Exhibition in Dresden last summer for their opinions on the adaptability of the educational methods observed there to our use in America. One reply which offers food for thought comes from our executive secretary, Homer N. Calver. He says after discussing several European museums and exhibitions:

My own thought growing out of these innovations in Europe is that you can do more with a permanent display as established in a museum than with the temporary health exhibit which is so familiar to us here. For teaching purposes, that is, for teaching children, teachers and medical or public health students, there is, it seems to me, the greatest need for a permanent museum. These museums would necessarily have to be different for each of the three groups concerned, different both as to subject matter and method of presentation. In addition there is the problem of popular health instruction through technic of display, but this, of course, should be quite different from any of the other three, although it may approach in some respects the displays for teachers of children. For such displays I am sure that it is necessary to keep in mind three fundamental principles—(1) there should be very little reading matter and what there is should be in large type, illustrated by attractive pictures; (2)

that as far as possible every item should be portrayed in three dimensions; and (3) that a large portion, probably fifty per cent or more, of the displays should be animated. The most important point of all is that animation should be brought about by some act (pushing a lever or turning a crank) of the observer.

It is far better to limit the scope of the exhibit to a few important ideas which can be shown in accordance with the above expressed principles than it is to cover a wide field with inadequate display.

Health Information with a Front Drive—They are building front-drive automobiles nowadays, because, the engineers assure us, it is easier to pull than to push.

Advertisers are "pulling" business by means of humor. Witness the cartoon of the astonished new father of triplets, who is advised to be nonchalant and to light a certain cigarette. Witness, also, that ragamuffin Skippy, whose "Road to Roam" sells a certain gasoline. And witness, further, John Held's Victorian wood-cuts, which promote a non-croaking cigarette.

The Health Education Division of the New York Tuberculosis and Health Association has tried this method, and found it good. Recently the Association went strictly modern, if humor be a modern invention, and published cartoons. The result is shown here. The drawings are by LeRoy Baldridge, nationally famous artist; the text was hammered out in this office. The results have been most gratifying.—Iago Galdston, M.D., Medical Information Bureau, New York Academy of Medicine.

During the summer play in the open Eat good foods. Sleep eight hours. Build up a reserve of good health.

Store up vitality and energy for the long winter months ahead.

Why Not Use What Has Been Prepared?—Unless one has a sure fire inspiration, why not reprint some of the best educational and publicity material already within reach? Millions of pieces of health educational material as issued by the original producer have

already been distributed by thousands of workers throughout the country. Large quantities have been re-published in the original form. Some items have been adapted to particular state or local needs.

Why not do more of direct re-publication or adaptation of material of unusual merit?

Are there ethical or other reasons for continuing to get out comparatively ineffective material in contrast with the very fine examples already issued from other sources?

This subject seems worthy of the most careful consideration. Will you write the editor? Discuss it in your local health council? Bring it up in publicity or health education sessions of classes in administration in public health training schools? In public health nursing schools? In various public health conventions?

A Well Organized Educational Campaign—"Hamilton County, Tenn., pellagra-free by June, 1931," is the goal which has been set by a committee of Chattanooga and Hamilton County.

Enlisting the help of local clubs, churches, industrial organizations, grocers, dairymen and newspapers, the committee has been able to reach every available group which would be a medium of education. . . . The city supervisor of home economics and the home demonstration agent, who is the supervisor of home economics in the county, were made joint chairmen of publicity and work with community clubs. As a result a definite study of foods which should be eaten to prevent pellagra has been undertaken by the home economics classes of the high schools. The sixth grades have also taken as their problem the study of "Foods That We Should Eat in Hamilton County and Chattanooga to Help Prevent Pellagra." . . .

In one rural community where many of the mothers as well as the men folk work in nearby industrial plants, many cases of pellagra have been found among the school children and their parents as well. In this community the home demonstration agent, at the request of her home economics class,

has helped to start a rat-feeding demonstration to prove the effects of a pellagra producing diet. . . . In other rural sections there are group meeting centers where each week the county Red Cross nutritionist is explaining diet for the cure and prevention of pellagra. The farm and home demonstration agents are stressing winter gardens and encouraging the ownership of cows and the use of their milk. As soon as the rural schools opened in August the teachers began to interest the children in having winter vegetable gardens at home. . . . For his part the county doctor keeps a card file of all cases of pellagra which are reported to him. His department is furnishing yeast to pellagrins who are unable to buy it, and he is trying to make yeast more available by encouraging druggists in the rural sections to carry it. . . .
—*Red Cross Courier*, Washington, D. C., Nov. 15, 1930. *Free*.

DIPHThERIA

"T.A.T. The Magic Medicine." *School Health*, Tuberculosis and Health Society, 51 Warren Ave., West, Detroit, Mich., Nov., 1930.

"Give Your Child A Chance!" Radio talk. New York State Dept. of Health.

"The Three Card Trick," a film issued by Medical Officer of Health. Town Hall, Holborn, London, W.C., England, as described in *Mother and Child*, Nov., 1930:

The first scenes of the film show the haunts of card-sharpers who may play the well-known three-card trick, with the practical impossibility of "Spotting the Lady." Fate often plays a similar trick in the game of life, and the odds against the child when diphtheria enters into the game are particularly heavy. The film then goes on to show the Schick test being applied, and the immunising treatment being given at the Holborn diphtheria immunisation clinic. Finally, three cards are shown—a memorial card to a child lost through diphtheria, then the wedding card she might have had if she had lived, and thirdly, the winning card—a certificate of successful immunisation signed by the Mayor of Holborn.

For the following items address Mrs. Marie F. Kirwan, State Charities Aid

Assn., 105 East 22d St., New York, N. Y.:

For several years Mrs. Kirwan has prepared for distribution at Health Education Headquarters at the A. P. H. A. convention a Chronological Report now brought up-to-date which covers organization activities and publicity material of the Five-Year New York State Diphtheria Prevention Campaign ending Jan. 1, 1931. 2 cents.

A new 24-sheet diphtheria prevention poster, 9½' x 20', depicting an appealing baby with upstretched arms posed against a vivid blue background with the wording "Parents! Toxin-Antitoxin Prevents Diphtheria." \$1.50 each. Free poster space in most communities can be obtained from your local outdoor advertising plant.

A double page leaflet containing reproductions of 22 diphtheria prevention posters, the work of high school students in a State-wide contest held in the high schools of New York State, can be obtained in quantities up to 5,000 for \$1.00 per thousand, plus postage. An extra large printing of these posters makes possible this offer. Better get a sample and see how it could be used in a state or city.

A 4-page brochure "Diphtheria and Its Eradication," by Dr. William H. Park. 2 cents.

RADIO HOURS

Wednesday, 11:15 a.m.—WCCO, Minneapolis and St. Paul. 810-370.2. Minnesota State Medical Assn.

Wednesday, 12:10 p.m.—WRJM, Racine. City Health Dept.

Wednesday, 7:00 p.m.—WGY, Schenectady, N. Y. State Dept. of Health, Albany, N. Y. Changed from 7:40 to 7:00 p.m.

Thursday, 12:40 p.m.—WAIU, Columbus, by Ohio Public Health Assn.

Thursday, 1:25 p.m.—WTIC, Hartford, Conn. Copies free. State Dept. of Health, Hartford.

Friday, 4:50 p.m.—WBZH, Boston, Mass. "Health Forum," by State Dept. of Public Health.

Saturday, 12:00 noon—WGN, Chicago, Ill. State Dept. of Public Health, Springfield, Ill. Mimeographed copies of talks on request.

Some New York State Dept. of

Health broadcasts: Is Open Air, Fresh Air? Off to Camp; Hang your Clothes on a Hickory Limb; Endurance Contests; Our Milk Supply; Save Milk For Our Children; Fresh Air in Industry.

REPORTING

The Ohio Public Health Association, Columbus, has issued a combined Service Report for 1929 and a Program of Service for 1930. In 1929 "General Educational Service" cost \$5,795.64, including Early Diagnosis Campaign, \$1,143.88, and "Child Health Education," \$2,380.26. The 1930 budget included General Education, \$6,332.95, Early Diagnosis, \$1,143.38, and Child Health Organization, \$2,917.57. The "Functions" for 1930 included 10 under "Education," and "... education ... are assumed to be carried on continuously within each" of the 8 major projects of the association.

"Facing A Social Challenge" is a 4-page report of Shoemaker Health and Welfare Center, 1041 Cutter St., Cincinnati. Of special interest to those doing work among Negroes. "Mimeographed copies of the detailed reports obtainable upon request."

It will happen: a state health association issues its annual report with no street address mentioned, and the headquarters city mentioned only once, in small type on the cover.

MAGAZINE ARTICLES

"The Cost of Medical Care," by Dr. O. R. Grogan. *Kiwanis Magazine*, Chicago, Nov., 1930.

"In Current Magazines," in *Semi-Monthly News Letter*, West Virginia State Dept. of Health. Brief mention of articles in professional and general magazines.

"Man's Dirty Clothes." *Literary Digest*. Oct. 11, 1930.

"'Prevention'—to Head Off Dis-

ease." *Literary Digest*. Nov. 8, 1930. Illus. Based on *Journal* article by Dr. H. E. Kleinschmidt.

"Ten Thousand Eyes Saved in Industry." *Literary Digest*, New York. Oct. 11, 1930. Illus. Based on press releases of National Society for the Prevention of Blindness.

HONORABLE MENTION

To Fargo Public Schools: for supplying addresses of publishers of books in reading lists in "Health Education," a course of study.

To American National Red Cross: for annual report with detailed table of contents, with paper and type for easy reading.

To Rockefeller Foundation: for annual report—type, paper, table of contents, and index (even though it overlooks school and popular health education).

To Child Hygiene Division, Indiana State Board of Health: for dating nearly all of a wide range of mimeographed information sheets and method helps issued for child health workers and volunteers.

EDUCATIONAL

Funeral Costs, by J. C. Gebhart. Committee on the Costs of Medical Care, Washington, D. C. 9 pages. *Free*.

Give Your Heart A Chance. Metropolitan Life Ins. Co., New York, N. Y. 10 pages. *Free*.

Infantile Paralysis. Metropolitan Life Ins. Co. 4 pages. *Free*.

Simply worded question-answer copy makes up a new series on syphilis and gonorrhea (5 English, 3 Italian) issued by Bellevue-Yorkville Health Demonstration, 325 East 38th St., New York, N. Y.

"Some Information for Mother," by J. P. Gavit. Illus. Re-issue. 15 cents. American Social Hygiene Assn.

Valentines—two of them—are already being marketed by American Social Hygiene Assn., 370 7th Ave., New York, N. Y. 5 cents each.

What a County Health Department Would Do For Dutchess County, Dutchess Co. Health Assn., Poughkeepsie, N. Y. 2 pages of question-answer text; organization diagram, 1 page.

Buying A Refrigerator, by M. E. Pennington. National Assn. of Ice Industries, 163 West Washington St., Chicago. 8 pages.

LISTS

Directories of state and city health officers appear in *Public Health Reports*, Nov. 14, 1930. Government Printing Office, Washington. 5 cents. The state list includes division and bureau heads, and house organs (the last is not complete).

DATES AHEAD

National Negro Health Week: announced to cover period including birth date of Booker T. Washington, April 5. It is not too early to be starting plans. Consult the 1930 manual in advance of the 1931 manual to be issued by the U. S. Public Health Service. The committee includes Asst. Surg. Gen. R. C. Williams, U. S. Public Health Service, and Dr. Monroe A. Work, Tuskegee Institute, Ala., who will answer questions.

The Gorgas Essay Contest for junior and senior high schools, public and private, will close January 25, 1931. The contests start in the individual local high school, followed by a state contest, and state winners to be entered for national honors and special awards, including \$500 and a travel allowance of \$250 for first place. It is important that any one interested write for details to Gorgas Memorial Institute, 1331 G Street, N.W., Washington, D. C.

BOOKS AND REPORTS

Mouth Infections and their Relation to Systemic Diseases—By *Malcolm Graeme MacNevin, M.D., F.A.C.P., and Harold Stearns Vaughan, M.D., D.D.S., F.A.C.S.* New York: Joseph Purcell Research Memorial, 1930. Price, \$4.00.

To meet the need of physicians and dentists a digest of the literature connecting mouth infections with systemic diseases is here given. The authors say:

In a critical review of the evidence supporting the oral focal infection idea, one is impressed with the limitations of every type of evidence submitted. It leaves one with the feeling that probably everybody contributing to the theory has been mistaken and that perhaps the idea at bottom is unsound. In pursuing the matter to a logical conclusion, one must admit that the proof submitted is not altogether conclusive.

The book is stimulating and will no doubt help in bringing about more accurate and careful investigations, as it cannot but convey dissatisfaction as to present knowledge.

The authors have traced in a very interesting manner the knowledge of mouth pathology and its effects on the body, giving evidences from paleopathology, Egyptian writings, Chinese medical lore, the Talmud, Hippocrates, Pliny, Galen, Walter H. Ryff (1544), who wrote the first dental monograph in the vernacular, to Pierre Fauchard, 18th century founder of modern scientific dentistry, who collected in a single work (1728) the whole doctrine of dental art to his time.

There is a short presentation of the problems of oral sepsis and of the pulpless tooth, followed by discussions of the evidences of oral focal infection, its

mechanism, extension, etc. The principal pathological oral conditions which have been shown to be sources of focal infection are listed. Diseases of the eye, ear, and other organs and systems are taken up in order. The later chapters are devoted to the normal mouth, pyorrhea, and caries.

The historical method is used. Critical comments are interspersed in a conservative manner. Since a second volume is to appear, it is hoped that it will contain both an author and subject index, lacking in the first.

The book shows a large amount of intelligent research. Each chapter is followed by references to the literature on the matters discussed. While the print is good, there is an astonishing number of errors.

The work is a distinct addition to our knowledge of a most important subject, which is too little understood and has been ridden to death on the one hand, but neglected on the other.

M. P. RAVENEL

Legal Anatomy and Surgery—By *Bernard S. Maloy, M.D.* Chicago: Callaghan & Co., 1930. 804 pp. Price, \$15.00.

The human body, Professor J. H. Wigmore tells us in his introduction, is constantly a subject of litigation. Since this is undeniably so, lawyers concerned with the many cases involving injuries and diseases must necessarily know something about the structure and operation of the human system. In this book they will find a lucid, accurate, and thorough description of anatomy, admirably set forth in simple and readable language, illustrated with numer-

ous excellent drawings and photographs.

Although the book is designed primarily for members of the legal profession, it should also be of value to sanitarians, especially those not possessing the medical degree, who desire to look up anatomical facts. It is well printed in large type and has a good index.

In addition to the introduction by Mr. Wigmore, a professor of law, there is another by Dr. W. A. Newman Dorland, who points out that this book is the only one of its kind, and that the author is to be congratulated on having produced a work of such great value. It is a reference book that can be commended to sanitarians whether they are involved in litigation or not.

JAMES A. TOBEY

Molds, Yeasts and Actinomycetes—

By A. T. Henrici, M.D. New York: Wiley, 1930. 296 pp. Price, \$3.50.

This is an excellent textbook for students beginning the study of mycology, as well as a handbook which will be of great assistance to laboratory workers in the fields of medical and industrial application and research.

The selection of the material from the confused and voluminous literature on molds, yeasts and actinomycetes is fortunate. The discussions are presented in an open, stimulating and interesting manner.

The first chapter deals with the structure and classification of the fungi. Since the relationship of the myxomycetes (slime molds) is not understood, and that of the bacteria in some doubt, the term fungi (when not qualified) includes the eumycetes or true fungi, i.e., the yeasts and molds. The actinomycetes seem to represent a transition between the bacteria and the molds and are therefore included in this presentation.

The second chapter considers methods for studying molds, yeasts and actino-

mycetes. Three chapters are devoted to molds; one to *Oidium* and *Monilia*, the fungi transitional between molds and yeasts; two to yeasts, and two to actinomycetes. The classification of the Fungi Imperfecti is discussed, and its difficulties shown.

The important animal and plant diseases caused by fungi are discussed, stress being laid on the distribution and symptoms of the diseases and the methods for isolation and identification of the causative organisms.

An exceptionally good chapter is that on the biological activities of the yeasts. It is presented from the historical standpoint, including the earlier chemical theories of alcoholic fermentation, the Liebig-Pasteur controversy, and a summary of the researches of Brown and Balls, who correlated the disappearance of sugar, the production of alcohol and carbon dioxide with the rate of growth of yeast cells. The nature, preparation and activity of zymase is discussed.

The two chapters on actinomycetes include not only their morphology and classification, but also the diseases in man, animals and plants caused by them.

The book is well printed, the illustrations good and numerous. Each chapter is followed by well selected references. It is a decidedly helpful and useful work, well done.

ESTHER W. STERN

An Introduction to Malariology—

By Mark F. Boyd. Cambridge, Mass.: Harvard University Press, 1930. 437 pp. Price, \$5.00.

Malaria workers all over the world will welcome this book, the title of which aptly gives its scope. The author has done his best work in intensive survey studies, and he leads the reader through successive stages of instruction to this end. A great amount of ascertained fact is presented in text, tables, and charts. He leaves (characteristi-

cally) speculative matter to quoted authorities, and there is no more of this than needed to bridge over what is still *terra incognita*.

The author is far in advance of existing practice, at least in the southern states. Many will differ with him as to the need for such thoroughness on the ground of cost and lack of trained workers, but unless carried out according to the methods outlined, a survey is largely guesswork. Field surveys in malaria correspond exactly to diagnosis in clinical medicine. The more thorough the diagnosis the more satisfactory the treatment. Quoting Darling (through Hackett) that the malariologist "had to learn to think like a mosquito," he follows the psychology of the mosquito through species, environment, climate and topography.

The author takes it for granted that the reader will understand the interchangeable use of the terms "malignant tertian," "*falciparum* infections," "estivo-autumnal malaria," and "subtertian." "Quartan tertian," page 54, obviously should be "quartan." The technic for Hastings's stain is incompletely quoted, leaving one in doubt as to whether the filtrate or the precipitate should be used. It would have been well to have mentioned that "daylite" lamps are unsuited to malaria work. Many will not agree that any of the Romanowsky stains are equally suitable for unfixed thick films. One would like to see more about thick film work, since they are so generally used in the field and so little understood in the laboratory. This applies especially to the description of the very good colored plates, which also might show more examples of parasites. The technic for dissecting mosquitoes is very good. A possible improvement would be to add a slight "stickiness" to the teasing medium.

The printing and make-up are excel-

lent, the illustrations abundant and good. Each chapter is followed by a well selected list of references. Dr. Boyd's work deserves the widest acceptance. He has fully justified the faith of those who know him in its production.

WILLIAM KRAUSS

Edward Jenner and the Discovery of Smallpox Vaccination—By Louis H. Roddis. Menasha, Wis.: George Banta Publishing Co., 1930. Price, \$1.00.

The life story of Edward Jenner is one of the most fascinating in all medical history. Beginning as a country practitioner with apparently no ambition for fame, he discovered, or at least made popular, the prevention of one of the most terrible scourges of the world. He will always be known as one of the greatest benefactors of the human race. Though it took a Pasteur, some 60 years later, to give the rational explanation of Jenner's discovery, this does not in the least detract from the credit due him. Anything concerning the life and work of Jenner is always welcome.

The author of the small volume before us has done a great deal of research, and has given to us in compact form a well and interestingly written story of smallpox prior to Jenner's time, the chief points in the life of Jenner, and the spread of the practice of vaccination. Needless to say, many points of interest which cannot be mentioned in a review are brought into these stories.

There is a good bibliography and a list of Jenner's publications, followed by several appendixes, which furnish handy statistics of the results of vaccination over 100 years, and the deaths in unvaccinated people compared to those vaccinated and revaccinated. The author gives in this material complete refutation of all objections which have been or are being raised against the

practice. The person who can read this book and still question the enormous value of vaccination has some peculiar mental twist, which renders him as insusceptible to reason as though he were dead.

The book is reprinted from the *Military Surgeon*. We owe a debt of gratitude to the author for giving it to us in this handy form. Unfortunately, the printing is not particularly good, there being a number of typographical errors, and the illustrations are not as clear as they might be. On page 147, the death of Sir Edward Jenner is given as 1923, though correctly stated on page 134. We hope for this volume a wide circulation. It can be commended unreservedly.

M. P. RAVENEL

The Healthy-Minded Child—*By Nelson Antrim Crawford, Karl A. Menninger. Coward-McCann, 1930. 198 pp. Price, \$1.75.*

One can hardly say too much in praise of this timely addition to the literature on mental health. It is worthy of rank as a companion volume to that classic of Dr. Thom's, *Everyday Problems of the Everyday Child*, and should be at the elbow of every consultant in child behavior. Whole chapters could be included unreservedly in prescriptions to inquiring parents. Most of the authors have the courage to give specific recommendations for management which are acceptable to the most critical exponents of mental hygiene principles of treatment. One may even say that the book is practically "foolproof." It is good to read again the familiar exposition of the meaning of mental health which cannot be repeated too often. We like the added thought that "it implies the actual betterment of both personality and environment," and again that (page 60) "With all of us our success or failure is fundamentally a matter of balance between our own innate personali-

ties and the difficulties of our environments."

The symposium includes contributions from those experienced in managing problems associated with the home, with the school and with other institutions associated in the promulgation of mental health principles. Specific instructions, ranging all the way from ascertaining motivation to alterations in environment, receive careful consideration.

Means of bringing about compatibility between an individual's desire for the expression of his personality and the requirements of his social setting are suggested by such recommendations as (page 78) "The important thing is to give the child the sense of successful activity," and (page 86) "the emotions generated by obstacles to the gratification of desire may acquire a dangerous force, which can be mitigated either by the gratification of the desire . . . or by the creation of new desires that can be gratified."

Two important fields of activity influencing the mental health of children, play and reading, receive particularly appropriate attention with specifically helpful information and guidance. So-called sex education receives expert handling, the discussion closing with an admonition that could well be carried over into other situations (page 182): "Most important of all, try to get an attitude toward the subject yourself of objectivity. . . . Whatever attitude you have will be unconsciously taken over by the child, regardless of the facts you may tell him orally. He will know how you feel, and he will imitate your emotion."

Perhaps the most impressive thing about the whole volume to the reviewer is the repeated but tactful insistence upon the importance of the parents' own attitudes toward their problems and their difficulties, as an approach to the

management and control of their children's behavior. With the richness of the material presented by most of the authors, the generalities of the chapters on "The Physical Basis of Mental Health" and "Mental Health in Youth" might have been omitted. This is a small, conveniently sized volume, in clear, easily readable type, remarkably light in weight for such a wealth of intellectually solid material.

HELEN P. LANGNER

The Filene Store. A Study of Employees' Relation to Management in a Retail Store—*By Mary Ladame. New York: Russell Sage Foundation, 1930. 541 pp. Price, \$2.50.*

The story of the relationship between management and the employee is to most social minded persons very interesting. Because of its long history and intelligent conduct the personnel program of the Filene Store (a Boston department store) is of especial interest and, more important still, of great value as a guide for other projects of a similar nature.

The present volume presents the results of a study of this personnel program in all of its details. It is very complete and discusses the structure of the association, hours of work and vacations, wages, profits, discipline, welfare work, the arbitration board—its advantages and disadvantages, representation, training of employees and many other important aspects of this problem. The study and report are impartial and highly objective, successes and failures each receiving their share of critical attention by the author. The book constitutes an excellent report of a careful and thorough study which should be of immense value in permanently recording many of the problems which arise in one of the most delicate of social adjustments—that between the employer and employee. LEONARD GREENBURG

Hygiene. A College Textbook for Non-Medical Students—*By R. C. Whitman, M.D. New York: Wiley, 1930. 327 pp. Price, \$2.50.*

A large number of books of the general type of the one before us has appeared during the past few years. The present reviewer groans at the announcement of a new book on hygiene designed for non-medical students. The present volume is distinctly better than the vast majority of the class to which it belongs.

The author states that it is designed to "stimulate reflection and ratiocination, rather than to paralyze the imagination," and describes his work as a "sort of jumble of the problems that the layman meets" in daily life.

In common with other recent books, considerable emphasis has been laid on heredity and eugenics. Twenty-five pages are given to "Endogenous Causes of Disease," and 37 pages to "The Hereditary Diseases of Man." What object has been achieved in listing 372 so-called hereditary diseases, we are not able to see. Under this heading are included anomalies and malformations of the eye, ear, skin, and other parts of the body, among which we find heterochromia, epicanthus, ectopia lentis, distichiasis, megalocornea, embryotoxon, dysostosis cleido-cranialis, etc. This list may not paralyze the imagination, but it certainly will not stimulate ratiocination, and mental indigestion must almost certainly result. We believe that it would have been better to have treated some of the diseases more fully and omitted practically all of this long list of so-called hereditary diseases over which we have no control and for many of which there is no remedy.

We also agree with the opinion of the author's friends given in the preface that there are too many technical and purely medical terms.

The author has succeeded in his aim

of "substantial accuracy," except here and there in his English; e.g., "A man is a man because his fathers were human beings, and a goose is a goose for the same reason."

The book is well printed and fairly well indexed. M. P. RAVENEL

A Compilation of Culture Media for the Cultivation of Micro Organisms—*By Max Levine, Ph.D., and H. W. Schoenlein, M.S. Baltimore: Williams & Wilkins, 1930. 969 pp. Price, \$15.00.*

Written at the request of the Society of American Bacteriologists and under a grant from the Digestive Ferments Company, this book is a compendium of information on culture mediums. It is in the arrangement of the material that the real value lies. About 7,000 formulas are classified into 2,543 quite distinct mediums, each of which is given a number and distinctive name. The descriptions are uniform, each medium being described under the headings: Constituents, Preparation, Sterilization, Use, Variants. The medium classification is based primarily upon physical state. Further classification is made on the basis of additional organic substances and, still further, upon the nature of the nitrogen and carbon sources. Four indexes—Medium Name, Constituents, Author and Use—facilitate the location of any particular formula. A complete list of references from which the formulas were gleaned constitutes an important feature.

To those historically minded, medium 2280a will have peculiar interest. In the *Use* index it appears under "Vibrio cholerae, isolation and cultivation of"; in the *Author* index, under "Koch, R."; in the *Medium Name* index, under "Koch's Nutrient Gelatin." The formula takes up only part of one column and the constituents are merely equal parts of any nutrient medium

(double strength) and gelatin solution 5 to 6 per cent—but Levine and Schoenlein's book would have been much thinner without this contribution of Robert Koch in 1881.

One is a bit startled to find that upon publication the compilation already lacks 4 years of being up to date. This, however, does not detract from its value as much as might at first be assumed, since the more recently published formulas are more available than the earlier ones.

As was inevitable, there are some omissions and minor errors, but as a whole the book is a valuable piece of work, unbelievably well done and a needed addition to the bacteriologist's reference library. We cannot but hope that the use made of this volume will be sufficient to justify the prodigious labor it must have involved.

PEARL KENDRICK

Nursing in Eye, Ear, Nose and Throat Diseases—*By A. Edward Davis and Beaman Douglas. (3d ed. rev.) Philadelphia: Davis, 1930. 373 pp. Price, \$2.50.*

This book has much to commend it for the lucid way in which the anatomy and technical procedures are described. It is short and concise but contains the essentials.

The subject matter is admirably handled as to divisions—anatomy, physiology, preparation of patient, operating room, instruments and after care. Description of disease and diagnostic signs have been touched lightly as is proper in this type of book.

The technic of operations, dressings, instruments and other paraphernalia, as described in this book, are in many instances those of 25 or more years ago, such as cold water coil, powder blowers and use of powders, packing the mastoid wound during dressings, the operation of ossiculectomy and many other things,

all of which were common but have been relegated to the archives. With a careful revision this could well be an admirable text. JOHN W. CARMACK

Adolescence. Studies in Mental Hygiene—By Frankwood E. Williams. New York: Farrar & Rinehart, 1930. 279 pp. Price, \$2.50.

Dr. Williams presents, in this book, a very human picture—human because any statement and any case illustration might well be ourselves or someone we know. This has been accomplished by the compilation of a series of individual papers, each with a comprehensively developed theme, and all having one common denominator unifying the group. That denominator is the consideration by educators (in the broad sense of the term) of the emotional development of the individual.

The goal is emotional maturity—adulthood—represented as a stage where “one is able to see realities in terms of what they are, cleared of all infantile symbolic investments; and where one is able to adjust to an unalterable situation with a minimum of conflict.”

This ideal is not presented as a panacea, but certainly a solution to many problems, since we do know that individuals are distorted, not by “witchery” but through human agencies. Examples of this are abundant in any walk of life—in the court, in the business, and in the home—wherever people in positions of authority make their decisions (as they do) in the light of their own unsolved childhood problems.

As if to justify this clear presentation of so painful a truth, Dr. Williams emphasizes the human quality and universality of “immaturity”—summarized in his last two lines “delinquency is a relative matter—no one is excluded.” He furthermore throws a small but brilliant light into the shadows that have

heretofore enveloped the problems of maladjusted individuals by giving a concise résumé of the accomplishments in the fields of delinquency, mental hygiene in colleges, and child guidance clinics, all of which indeed marks the beginning of the new understanding of human behavior and the new approach for modification as well as prevention.

LILLIAN MALCOVE

Ergebnisse der Sozialen Hygiene und Gesundheitsfürsorge—By Prof. Dr. A. Grotjahn, Prof. Dr. L. Langstein, and Prof. Dr. F. Rott. Leipzig: Verlag Georg Thieme, 1930. Vol. 2, 497 pp., 27 figs. in text. Price, unbound 36 marks, linen 38 marks.

The second volume of this treatise on social hygiene and health conservation is very largely concerned with more or less definite social movements in the interests of health. The 13 chapters, each by a specialist, are all comprehensive and well documented. Among the subjects treated are social environment and heredity with illustrations drawn from “one egg,” i.e., identical, and “two egg,” i.e., not identical twins, with the conclusion that eugenic measures to limit the defective and to conserve the normal are desirable.

The value of periodic medical examination in the conservation of health is presented in an extensive historical review in which American data loom large.

The hygiene of recreation and convalescence in children is treated wholly from German data and largely with reference to tuberculosis. The school feeding of children and dietaries used in hospitals are discussed with reference to organization, diversification, and costs.

The epidemiology and sanitary regulation of poliomyelitis are very effectively presented with graphs of age-incidence, mortality, and comparisons of different localities. German procedure in isolation and disinfection is outlined.

The new German mortality tables are presented and the system of reporting sources of venereal infections recently established in Berlin is explained. It has resulted in large increase in cases detected and brought under medical care in the early stages. The lack of progress in the last half century in the control or elimination of alcoholism is deplored.

CHARLES A. KOFOID

Hieronymus Fracastorius. Contagion, Contagious Diseases, and Their Treatment—By Wilmer Cave Wright, Ph.D. New York: Putnam, 1930. Price, \$4.50.

All lovers of medical history will welcome the appearance of this volume, which is No. II of the "History of Medicine Series" issued under the auspices of the Library of the New York Academy of Medicine. It comes out on the 400th anniversary of the publication of the earliest medical work of Fracastorius, the well-known poem on syphilis—"Syphilis sive Morbus Gallicus."

Fracastorius has a number of claims to greatness. His name will always be one of the great ones in medical history. Two things will be remembered by everyone, either one of which would have insured his fame. As said by Colonel Garrison, his work *De Contagione* "contains the first scientific statement of the true nature of contagion, of infection, of disease germs and the modes of transmission of infectious diseases."

Whatever may have been the origin of the term syphilis—and volumes have been written on the subject—to Fracastorius we owe the poem of that name, which has been described as "divine" even by one of the severest of critics, and also the general adoption of the name for this widespread disease. Practically all critics are eulogistic in writing of this poem. After his death, the Coun-

cil of Verona voted him a marble statue, and stated that in poetry he had surpassed all of his contemporaries. The poem also contains a vast amount of information, though his most notable contribution to our knowledge of syphilis is contained in three chapters of his prose book, *De Contagione*, published 16 years later.

In the volume before us, 44 pages are given to an introduction, which is a clear and scholarly description of Fracastorius himself and his work, together with the opinions of contemporaries and those who came later. The larger part is devoted to his ideas on contagion, 62 pages; the contagious diseases, 102 pages; and their treatment, 160 pages. The left hand pages are in Latin, the right giving the English translation.

The number of subjects treated by Fracastorius is remarkable, and all show great powers of observation and deep knowledge of disease.

Few medical men will be able to criticise the translations, and fewer still have at hand the originals which have been consulted by the translator. However, the book bears every evidence of careful study and masterful knowledge. Forty-two pages are devoted to notes which make clear the amount of study which the translator has given. Finally 6 pages are devoted to a bibliography. The preface states that the present translation of *De Contagione*, published in 1546, is the first which has appeared in English.

It is hard to speak too highly of the character of the work which has been done in the preparation of this volume, and the learning which is evident on every page. The printing and binding are excellent, the whole making up what all must recognise as a valuable addition to any library.

M. P. RAVENEL

HEALTH DEPARTMENT AND OTHER REPORTS

IRA V. HISCOCK

Trenton, N. J.—A new annual report, that of the Trenton Bureau of Health, for the year 1929, is placed on the honor list of the year. An attractive cover bearing the city seal, the title "Trenton, New Jersey's Historic Capital City," a good photograph of the municipal building, an ingenious map showing the relation of the city geographically and according to population to the rest of the United States, and organization charts, prepare the reader for the current report of activities.

This city, with a population of 122,610, and an area of 7.7 square miles, had an appropriation in 1929 of \$112,188 for health work. About one-fourth of the population is foreign-born, the principal foreign groups being Italian, Polish, Hungarian, Russian and English. A birth rate of 22.8 and a resident mortality rate of 11.7 are recorded. There were 44 cases and 4 deaths from diphtheria as compared with 1,505 cases and 105 deaths in 1923. A total of 17,771 children were immunized or shown to be Schick negative during the year. Trends of mortality from various causes are shown by charts accompanying descriptive text.

The planning and assignment of the clerical work of the sanitary division, together with the reception of reports, checking, sending out notices and issuing licenses, is done under the supervision of the registrar of vital statistics, who is also the chief clerk of the department. A chief sanitary inspector supervises the inspection activities. Of 5 sanitary inspectors, one is assigned to communicable disease control and the investigation of complaints. The other 4 inspectors cover certain specified dis-

tricts in the city and make routine inspections of all classes of business involving sanitary and food control measures. There are over 1,500 such places under regular inspection. About 97 per cent of the milk supply is pasteurized, 1 per cent is certified, and the remainder is from tuberculin tested herds.

Infant mortality is analyzed by wards, as well as for the city as a whole. The city rate of 70.8 is contrasted with a rate of 129.9 in 1918. During 1929 there were 408 home nursing visits to prospective mothers, 11,841 visits to first year babies, 8,999 to second year babies, and 11,583 visits to other preschool children. Visits to baby and preschool clinics numbered 12,371. Maternity and boarding homes are also supervised.

Cincinnati, O.—The Cincinnati Social Hygiene Society has rendered a mimeographed report for the year ending May, 1930, which analyzes the field of social hygiene on a community basis and discusses progress. The outstanding achievement is considered the establishment of a course of sex-education for teachers, nurses and leaders at the University of Cincinnati under the auspices of the College of Education and the Social Hygiene Society, with a teacher from the American Social Hygiene Association. There was an enrollment of 60 pupils, and full credit was given toward graduate and undergraduate degrees.

Other educational measures of the Society included special lectures, 148 with attendance of 16,000, study groups, exhibits (once a week during Negro Fair at Church—over 300 pieces

of material distributed) and radio talks. Legal protective measures included co-operation with the Juvenile Court and Police Court with the follow-up work under the Department of Public Welfare. Under medical measures a pamphlet of the U. S. Public Health Service on modern treatment was sent through the Academy of Medicine to physicians, and conferences were held with the clinics. Special attention was given to a Children's Clinic where 1,254 treatments were given.

Haverhill, Mass.—According to the seal on the cover of this annual report of the board of health for 1929, this city was settled in 1640. The health department was organized 50 years ago. Now with a population of 45,467, a resident death rate of 11.9, a birth rate of 17.8 and an infant mortality rate of 42.08 are recorded. The outstanding low rate was for tuberculosis—21.99.

The expenses for the year amounted to \$73,008, or three and four-fifths cents of every dollar raised by taxation for current city expenses. Fifty-six per cent of the money expended was in connection with tuberculosis work including hospitalization. The health department has 535 cases on the register of whom 65 are hospitalized.

New Mexico—New Mexico's 6th report of the Bureau of Public Health for 1929-1930 opens with a table of contents followed by a series of charts showing progress since public health work was organized on a state-wide basis in 1919. The personnel has increased from 4 to 16 and the funds from \$18,000 a year to \$104,000. Public health laboratory specimens have increased from 3,351 to 15,167.

Diphtheria prevailed in many parts of the state in 1919 and was accepted as inevitable. In 1920 there were 1,399 cases. In 1921 toxin-antitoxin was introduced and the number of cases fell

77 per cent within 5 years. There were 372 cases in 1929. During the same period smallpox cases decreased from 316 to 82. Over 40 per cent of the population is now served by full-time county health departments, while public health nurses have increased in 9 years from 4 to 35. This is a noteworthy record of progress. Admission of the State to the U. S. Birth and Death Registration Areas for 1929 marked the culmination of 10 years of effort.

Montclair, N. J.—Among the year's outstanding events are plans developed to strengthen public health nursing work of the official and voluntary agencies by the employment of a coordinating nurse, the employment of a venereal disease control nurse and the continuance of diphtheria prevention work. In 1929 there were 13 cases of diphtheria with no deaths as compared with 40 cases and 3 deaths in 1928.

This city with a population of 40,264 in 1929 (68.5 per cent native white) reports a death rate of 9.4. Nearly all the deaths were of persons 79 years of age or older. An infant mortality rate of 43.5 is creditable and the report refers to the value of the prenatal and postpartum service rendered. Of 574 resident births, 432 occurred in hospitals, and only 21 were attended by midwives. An active well baby clinic service is described.

Colombo, Ceylon—The principal features of the 1929 report of the medical officer of health are several unusually effective spot maps of plague, enteric fever and phthisis, and a detailed analysis of the typhoid fever problem. These spot maps are carefully prepared on a special grade of paper, and the characteristics of the city as well as the location of cases of various kinds by colored dots stand out clearly and add interest to the report. Several excellent charts facilitate an understanding of

special problems, such as the influence on the annual incidence of enteric fever over a long period of years of increased connections of premises with the public sewer.

The chief sources of typhoid infection are shown to be from carriers and from cases diagnosed and notified late in the course of the disease. The most common modes of transmission are by indirect infection through, in the order of importance, (1) fingers, food, mouth; (2) flies, food, mouth; (3) soil, fingers, food, mouth; and less commonly (4) water, mouth, or water, food, mouth.

New Zealand—For the year 1929–1930, the annual report of the Director-General of Health reports a death rate for the Dominion of 8.49, an infant mortality rate of 34.1, a birth rate of 19.0 and a tuberculosis rate of 45.6. The report opens with a discussion of the effects of birth control measures on society and national progress.

It is interesting to note a recom-

mendation for the adoption of national insurance for sickness and invalidity. "It is one method already in operation in England, and throughout Europe and Asia, of partnership with the general medical practitioner for the purpose of disease prevention." Special investigations recorded include a report on a dysentery outbreak in the Auckland district; further results of investigations into problems of stillbirths and neonatal deaths; a survey of physical education in schools; a study in comparative health of Maori and Pakeha children; and a survey of menstrual functions of training-college students and high school girls. It is concluded that there is need for the care and supervision of the young girl through puberty, adolescence to young womanhood. Overtaxing of the bodily strength with study, too great mental strain, too little sleep, lack of practice of the laws of general hygiene, may produce irreparable injury affecting both body and mind.

Serum Tests for Syphilis—Of the many comparisons between the Kahn and Wassermann tests that have been reported upon from time to time, this seems to be the most exact. In a lim-

ited quantitative series, the Kahn test was found 12 per cent more positive than the Wassermann.

SCHWARTZ, S. C. A Comparison of the Wassermann and Kahn Tests by Means of a Quantitative Method. J. Lab. & Clin. Med. 16, 2: 197 (Nov.), 1930.

Common Cold Etiology—Controlled experiments with the chimpanzee and man show that an uncultivable, filtrable agent found in nasal washings of persons with colds will produce the disease when instilled into the healthy nostril. A very convincing demonstration.

SHIBLEY, G. S. Studies of the Etiology of the Common Cold. J. A. M. A. 95, 21: 1553 (Nov. 22), 1930.

Delay in Entering Sanatoriums—A year elapsed from date of first symptoms before half the patients (in group studied) were admitted to tuberculosis sanatoriums for treatment. Other significant findings are recorded.

WILLIAMS, L. R., and HILL, A. M. The Loss to Time Before a Tuberculous Patient is Admitted to a Sanatorium. New Eng. J. Med. 203, 20: 961 (Nov. 13), 1930.

Normal Serum and Poliomyelitis—Serum from adults and city children neutralized poliomyelitis virus to a greater degree than did that of convalescents. Serum from rural children and infants was practically without immunizing power. The findings suggest that immunity to polio develops similarly to immunity to diphtheria and that normal adult serum may prove as effective therapeutically as convalescent serum.

SHAUGHNESSY, H. J. The Neutralization of Poliomyelitis Virus by Human Serum. J. Prev. Med. 4, 6: 463 (Nov.), 1930.

NEWS FROM THE FIELD

BUST OF LOUIS PASTEUR SENT TO UNIVERSITY OF PENNSYLVANIA

A BRONZE portrait bust of Louis Pasteur, through the will of Arthur C. Hugenschmidt, D.D.S., a friend of the famous scientist, who died in Paris last year, has been sent to the University of Pennsylvania. Dr. Hugenschmidt, dentist to Pasteur, was presented with the bust by Madam Pasteur after her husband's death.

JEFFERSON COUNTY HAS NEW BUREAU OF HEALTH EDUCATION

THE Jefferson County Board of Health of Birmingham, Ala., announces the establishment of a new Bureau of Health Education and Publicity, with K. W. Grimley as first Director.

WORLD CONFERENCE ON WORK FOR THE BLIND

PRESIDENT Hoover has invited 52 nations to participate in a World Conference on Work for the Blind in New York City next April. This Conference has been called upon authorization by Congress, and will be held under the auspices of the following organizations: American Foundation for the Blind, American Association of Instructors of the Blind, and the American Association Workers for the Blind.

CONGRESS OF THE ROYAL INSTITUTE OF PUBLIC HEALTH

THE next annual Congress of The Royal Institute of Public Health will be held in the City of Frankfurt-on-Main from Tuesday, May 19 to Sunday, May 24, 1931, on the invitation of the German Government, the Municipality and the University of Frankfurt.

To this International Congress delegates are being invited from the Governments, the Municipalities, the Universities, and other Public Bodies of Great Britain and Ireland and the British Dominions, as well as from Continental and Foreign Countries.

DR. LANDSTEINER WINS NOBEL PRIZE

DR. Karl Landsteiner, bacteriologist and pathologist on the staff of the Rockefeller Institute for Medical Research, New York, who was awarded the Nobel Prize for Medicine, was born in Vienna, graduated at the University of Vienna in 1891, and was pathologist there from 1909 to 1919. He has been a member of the Rockefeller Institute for Medical Research since 1922. The prize amounts to about \$48,000. The award was based on Dr. Landsteiner's research in connection with blood groups. He is known also for his research on infantile paralysis, paroxysmal hemoglobinuria, and blood serum in relation to immunity. The only other American to have received the Nobel Prize for Medicine was Dr. Alexis Carrel, to whom it was awarded in 1912.

CONFERENCE DISCUSSES HEALTH OF NEGROES

A CONFERENCE of health and welfare workers was held in Washington, October 29 to consider ways of controlling the high mortality of colored people. An executive committee was named to consider a year-round health movement, with George W. Bowles, M.D., as chairman. Plans were made for the next National Negro Health Week, which includes the birth date of Booker Washington, April 5.

NATIONAL COMMITTEE FOR MENTAL
HYGIENE PLANS

THE development of a nation-wide program of research in coöperation with American universities as a next step in the extension of the activities of The National Committee for Mental Hygiene was announced as a major objective for the near future at a luncheon held November 13, 1930, in New York City, in celebration of the Committee's twenty-first anniversary. The effort will be made under the leadership of Dr. C. M. Hincks, who was introduced as the new General Director of the organization, succeeding Dr. Frankwood E. Williams, who will retire on January 1 after 14 years of service.

GRANTS TO TWO FACULTY MEMBERS OF
UNIVERSITY OF SOUTHERN CALIFORNIA

GRANTS have been made to two faculty members of the School of Medicine of the University of Southern California, Dr. Harry J. Deuel and Dr. Clinton H. Thienes, by the National Research Council and the Committee on Scientific Research of the American Medical Association, for the purpose of research in the determination of the antiketogenic value of different carbohydrates.

Dr. Thienes also received a grant of \$500 from the American Medical Association for research in "The Relationship Between Myenteric Plexus and Ganglia and the Mesenteric Nerves."

YELLOW FEVER SACRIFICE MAY NET
DOUBLE PENSION

PRIVATE William H. Dean of the cavalry died after submitting to yellow fever tests in behalf of science. Now Representative Mapes of Michigan has put in a bill to give both his father and mother a pension of \$62.50 a month, and to have Dean's name inscribed on the War Department's roll of honor.

DR. RAVENEL NAMED TO STATE BOARD

DR. R. Mazzyck P. Ravenel, professor of medicine, bacteriology and preventive medicine in the University of Missouri, Columbia, Mo., has been appointed consultant in public health and medical education by the Missouri State Board of Health at a meeting in Jefferson City, December 2.

INTERNATIONAL HOSPITAL CONGRESS

THE International Hospital Congress to be held in Vienna, June 8-14, will bring together men and women interested in hospital work for an interchange of ideas, comparison of practices and proceedings, methods of administration and hospital building costs and economy.

Technical papers will be presented by outstanding authorities on hospital work from throughout the world.

Tours are being offered under the management of the American Express Company. These tours are designed to include visitations to hospitals and hospital laboratories in various cities of Europe en route.

Details may be obtained from Dr. E. H. Lewinski Corwin, Secy. Gen'l, International Hospital Committee, 2 East 103d St., New York, N. Y.

NEW

The staff of the Steiner Cancer Clinic at Atlanta, Ga., has begun the publication of a monthly bulletin devoted largely to cancer case histories.

PERSONALS

DR. ALAN GREGG has been appointed Director for the medical sciences of the Rockefeller Foundation. He will occupy the position vacated by the death, February 16, of Dr. Richard M. Pearce, Jr.

DR. W. ROSS CAMERON, Director of the Berkeley (W. Va.) County Health Unit has resigned to become director of the Washington County (Md.)

Health Department. He is succeeded by Dr. Edwin Cameron from Kentucky.

RUBY H. MANTER of Duluth, Minn., has been appointed to the position of Assistant Bacteriologist in the Maryland State Department of Health.

DR. KATHARINE B. DAVIS is planning to retire to Asilomar, Calif., where she will live with her two sisters. For thirteen years she was superintendent of the New York State Reformatory for Women, establishing the first scientific studies of the physical, mental, social and moral conditions of each inmate. She was the first and only woman to be Commissioner of Correction in New York City. She was chairman of the Parole Board. During the war she worked with the Commission on Training Camp Ac-

tivities. And for the last ten years she has been general secretary of the Bureau of Social Hygiene. Dr. Davis is author of "Factors in the Sex Life of Twenty-Two Hundred Women."

CONFERENCES

Jan. 23-24, American Social Hygiene Association, New York, N. Y.

Mar. 23-27, College of Physicians, Baltimore, Md.

Apr. 2-4, Association of Anatomists, Chicago, Ill.

Apr. 14-20, World Conference on Work for the Blind, New York, N. Y.

Apr. 13-16, American Red Cross, National Convention, Washington, D. C.

June 1-5, Psychiatric Association, Toronto, Can.

Number 2

Water-Borne Typhoid Fever Still a Menace*

ABEL WOLMAN, F. A. P. H. A., AND ARTHUR E.
GORMAN, F. A. P. H. A.

*Chief Engineer, Maryland State Department of Health, Baltimore, Md.; and
Wallace & Tiernan Co., Inc., Newark, N. J.*

THE phenomenal decline in the typhoid fever death rate in North America and Europe since the beginning of the 20th century is well known to every health and water works official. Its general trend in the United States is indicated in the 5-year rate table for the U. S. Registration Area:

Year	Deaths per 100,000
1900	35.8
1905	27.9
1910	23.5
1915	12.8
1920	7.9
1925	8.0
1928	4.9

The knowledge of this statistical decrease has unfortunately developed in many places among health and water works officials, and even the general public, an element of tolerance toward this disease and a laxity in control measures which constitute a potential public health hazard. It may be true that as control and preventive measures become better perfected, the cost of carrying them on may be decreased and money may economically be diverted to other public health work. But laxity in control, especially of milk and water, is likely to be reflected in sudden and intense outbreaks of large proportions.

For example, in spite of the rapidly declining typhoid fever death

* Read before the Public Health Engineering Section of the American Public Health Association at the Fifty-ninth Annual Meeting at Fort Worth, Tex., October 28, 1930.

rate on this continent and in Europe, 3 of the largest epidemics on record occurred in the last decade:

TABLE I

Place	Population	Date	Typhoid Fever		Infection
			Cases	Deaths	
Hanover, Germany	427,280	Sept.-Dec., 1926	2,423	545	Water Borne
Lyons, France	600,000*	Jan.-Feb., 1929	2,143*	45*	" "
Montreal, Canada	600,000	March-July, 1927	5,014	488	Milk "

* Incomplete record.

The question might well be asked—If typhoid fever is likely to become almost extinct in the present and coming generations in large centers of population, will a lessened immunity result? If so, in the future outbreaks of this disease, are we likely to have a mortality rate much higher than ever before? If such is the probability and explosive outbreaks of the nature of the 3 cited can occur at this late date, when the arts of water purification and dairy sanitation have reached such a high degree of development, something must be wrong with the control measures.

TABLE II

United States

FIGURE I

The control is primarily a responsibility of the health officer, for in a large percentage of cases he has the police power which the courts will sustain. He can insist on the elimination of potentially dangerous conditions and the exercise of the necessary precautionary control measures to provide against emergencies, which might be anticipated, provided reasonable inspection is maintained and recognized standards of performance are enforced.

In order to obtain facts concerning water-borne outbreaks in Canada and the United States and their relationship to the factors over which public health and water works officials have jurisdiction and control, we have made a careful study of the outbreaks which have occurred during the last decade in these countries.

Figure I shows the marked decline in the typhoid fever death rate in the U. S. Registration Area for this decade, which opened with a rate of 35.8 and showed a steady decline to 4.9 per 100,000 in 1928, with the exception of the year 1925. For this year nearly one-third of the states reported increases in their typhoid death rates.

The decade 1920-1929 was selected as representing an era in which knowledge was available for adequate purification of water supplies and for proper protection of these supplies against those hazards reasonably and practicably susceptible to control. The information was obtained from the various state and provincial health departments whose courteous and complete coöperation is herewith acknowledged. These reports were studied, particularly with ref-

erence to identifying the causes of outbreaks and determining therefrom where control measures had failed or were most needed.

Reports were received from 47 states in the United States and 6 provinces in Canada. The United States reports represent 98.65 per cent and the Canadian 79.5 per cent, respectively, of the population of these countries. The only state not reporting was South Carolina. The investigation brought forth the facts summarized in Table II.

The number of outbreaks in the United States shows a distinct increase for the year 1927, rising from 21 in 1926 to 31 in 1927 and dropping to 19 in 1928. This was the year of heavy floods, especially in the Mississippi River valley. These high waters affected water supplies in many states. In Canada, 1923 was the high year for water-borne outbreaks, with 1926 the low. In both the United States and Canada there was an increase in the number of outbreaks in 1929 over previous years. The greatest number of deaths from typhoid fever occurred for the United States in 1920 and for Canada in 1923, reflecting the well known water-borne epidemics at Salem, O., and Cochrane, Ont., respectively.

In Table III the distribution of the 282 outbreaks into population groups indicates, as might be expected, that the larger number occurred in the small cities.

TABLE III

OUTBREAKS OF WATER-BORNE DISEASES IN THE UNITED STATES AND CANADA, CLASSIFIED AS TO POPULATION GROUPS AFFECTED—DECADE 1920-1929

<i>United States</i>		
Population	Number of Outbreaks	Per Cent of Outbreaks
1,000 and under	68	28.1
1,000 to 5,000	89	36.8
5,000 to 10,000	30	12.4
10,000 to 25,000	29	12.0
25,000 to 50,000	11	4.6
50,000 to 100,000	6	2.5
100,000 to 500,000	7	2.8
500,000 to 1,000,000	0	0.0
Over 1,000,000	2	0.8
	<hr/> 242	<hr/> 100.0
<i>Canada</i>		
1,000 and under	6	15.0
1,000 to 5,000	25	62.5
5,000 to 10,000	4	10.0
10,000 to 25,000	5	12.5
	<hr/> 40	<hr/> 100.0

Of the outbreaks in the United States 64.9 per cent, and of those in Canada 77.5 per cent, were in cities having a population of under 5,000. In both countries this appears to be the group needing the greatest attention and supervision. In the United States 4 of the 10 largest typhoid outbreaks and 5 of the 10 largest dysentery outbreaks of the decade occurred in cities of this group. In Canada 8 of the largest typhoid outbreaks were in cities of this group. These facts indicate a distinct need for better supervision over water supplies of the small and moderately small towns.

While we are emphasizing the need for better control in the smaller towns we should, however, note that 2 outbreaks occurred in cities having a population of over one million, where it may be presumed adequate finances were available to provide strict supervision over the quality of the public water supply.

For the purpose of this study the causes of these outbreaks were classified into 7 major groups each with minor subdivisions, making a total of 26 causes. Of these 7 major classifications, 6 relate to points in the water works system from the source of supply to the consumer's tap. The 7th includes a miscellaneous group not readily classified elsewhere. The classification is shown in Table IV A.

Table IV summarizes these findings and presents information worthy of careful study by health and water works officials.

The largest number of outbreaks in both the United States and Canada was due to the use of untreated surface water supplies. This was to be expected if one bears in mind the widespread pollution of surface water in these countries. In the United States the second largest number of outbreaks—57—was caused by the use of untreated ground water. In a majority of these—30—the sources were shallow wells polluted from surface sources.

It is worthy of note that, whereas the use of untreated surface and well water was responsible for 52.1 per cent and 55 per cent of the outbreaks in the United States and Canada respectively, the percentage of total typhoid fever cases in Canada due to the use of raw water was almost twice that in the United States—64.1 to 33.3.

One of the most important and significant findings in this study is the fact that in the United States, and to a lesser degree in Canada, water-borne outbreaks during the past decade have been due almost as much to laxity in handling water from its source to the consumer as to the use of water from polluted sources. This is a strong indictment of our methods of supervision and control and deserves very serious consideration by health and water works officials. In the United States, excluding the 14 outbreaks for which the cause is unknown,

TABLE IV

CLASSIFICATION OF WATER-BORNE OUTBREAKS IN THE UNITED STATES AND CANADA 1920-1929
INCLUSIVE, AS TO POINT OF POLLUTION IN WATER WORKS SYSTEM

Classification	<i>United States</i>						Total Cases of	
	Out- breaks	Per Cent	Cases of Typhoid	Per Cent	Cases of Dysentery	Per Cent	Typhoid and Dysentery	Per Cent
Untreated Surface Water Supplies	69	28.5	1,506	16.0	590	0.7	2,156	2.3
Untreated Ground Water Supplies	57	23.6	1,606	17.3	13,936	16.5	15,542	16.6
Contamination of Reservoirs and Cisterns	5	2.1	68	0.7	1,269	1.5	1,337	1.4
Inadequate Control Over Water Purification Methods	49	20.2	1,975	21.1	48,725	57.8	50,700	54.1
Contamination in Distribution System	31	12.8	2,055	21.9	6,535	7.8	8,590	9.2
Contamination in Collection or Conduit System	17	7.0	1,883	20.1	11,810	14.0	13,723	14.7
Miscellaneous	14	5.8	274	2.9	1,450	1.7	1,664	1.7
<i>Totals</i>	242	100.0	9,367	100.0	84,345	100.0	93,712	100.0
<i>Canada</i>								
Untreated Surface Water Supplies	19	47.5	1,818	61.1				
Untreated Ground Water Supplies	3	7.5	45	1.6				
Contamination of Reservoirs and Cisterns	1	2.5	42	1.5				
Inadequate Control Over Water Purification Methods	8	20.0	433	15.3				
Contamination in Distribution System	6	15.0	214	7.5				
Contamination in Collection or Conduit System	3	7.5	284	10.0				
<i>Totals</i>	40	100.0	2,836	100.0				

the records show that 102 of a total of 228 outbreaks, or 44.7 per cent, were due to contamination occurring in the collection, delivery, or storage, or laxity in treatment. For Canada this percentage is 40.5.

The indications are that, in a high percentage of these cases, outbreaks could have been prevented by adequate inspection and control measures. Perhaps the most obvious case reported is that of one of

TABLE IV A

CLASSIFICATION OF CAUSES FOR WATER-BORNE TYPHOID FEVER FOR THE UNITED STATES AND CANADA DURING THE DECADE 1920-1929 INCLUSIVE

A. Surface Water Supplies—

1. Contamination of brook or stream by pollution on watershed
2. Use of polluted river water—untreated
3. Use of polluted lake water—untreated
4. Contamination of spring well or infiltration gallery by pollution on watershed
5. Contamination of spring well or infiltration gallery by flood waters

B. Underground Water Supplies—

1. Surface pollution of shallow wells
2. Faulty well casing or construction
3. Pollution of deep well from adjacent river or lake
4. Pollution of well from adjacent sewer or sewage tank
5. Underground pollution of well or spring in creviced limestone
6. Underground pollution of well or spring, source unknown
7. Underground pollution of well by surface contamination through abandoned well
8. Overflow of sewer or flood water into top of well casing

C. Reservoirs or Cistern Storage—

1. Seepage from sewer or surface into cracked cistern or reservoir

D. Water Purification—

1. Inadequate control of filtration and allied treatment
2. Inadequate chlorination—when only treatment
3. Interruption of chlorination—when only treatment

F. Distribution System—

1. Pollution of water mains during construction or repairs
2. Leaking water and sewer in same trench
3. Cross-connection with polluted water supply
4. Break in supply main in river crossing

G. Collection or Conduit System—

1. Auxiliary intakes to polluted source
2. Seepage of surface water or sewage into gravity conduit

H. Miscellaneous—

1. Use of polluted private supply because of objectionable taste or quality of public supply
2. Use of polluted water not intended for drinking purposes
3. Cause of outbreak undetermined
4. Data insufficient for classification

America's largest cities, Detroit, where in spite of the fact that the city was equipped with one of the most modern rapid sand filtration plants, in February, 1926, it suffered an outbreak of water-borne dysentery amounting to at least 45,000 to 50,000 cases.

A balanced picture of the situation cannot, however, be obtained from a study of the number of outbreaks. Let us analyze the data by persons affected as indicated in the cases of typhoid and dysentery reported. Of the typhoid cases 43.7 per cent, and of the dysentery cases 66.1 per cent, were due primarily not to the use of polluted water at its source, but to laxity in source treatment or distribution methods.

It is, of course, a recognized fact that the use of surface or ground waters subject to pollution and without adequate purification treatment is an invitation to water-borne outbreaks. But when water is

known to be polluted and in consequence of this purification methods have been provided, is it not a serious reflection on both water works and health officials to have outbreaks of typhoid fever and dysentery occur? In the United States 2,055 cases of typhoid fever occurred because of pollution of an apparently safe water as it was being distributed to the consumer. Of these, 1,995, or over 95 per cent, were due to unprotected cross-connections with polluted water supplies. Among these were the disastrous outbreaks at Winona Lake and Fort Wayne, Ind., and Bloomington, Ill.

Inadequate control over purification methods accounted for 1,925 cases. Of these, 395 were cases where treatment consisted of filtration and chlorination—a combination capable of giving protection against heavily polluted water if efficiently operated. Inadequate chlorination, where this treatment was the sole protection, was responsible for 985 cases. This clearly indicates lack of proper control measures. Among these outbreaks were those at Newport and Covington, Ky., Akron, N. Y., Delaware, O., and Salt Lake City, Utah. In the residual chlorine test, plant operators have at their command an effective method of controlling chlorination to give complete public health protection. With proper control measures all of these cases could have been prevented.

Seventeen outbreaks in the United States, representing 594 cases of typhoid fever, were due to interruption in chlorination where this was the only safeguard against contamination. In 6 instances the chlorinator was out of order and in the others it had been shut down. In Pittsburg, Calif., Alpena, Mich., and Greeneville, Tenn., were the outstanding outbreaks of this group. The reliance on one chlorinator where chlorination is the sole line of defense against a potentially dangerous water supply has always been considered a serious error, but the shut-down of chlorination under these circumstances is little short of criminal negligence. These are facts which health and water works officials must face, for the responsibility is theirs.

The number of typhoid fever and dysentery cases resulting from contamination in the system for collection and transmission of raw water was high in both the United States and Canada. Auxiliary intakes were responsible for 4 outbreaks in the United States, representing 2,300 dysentery and 69 typhoid cases. Sewage pollution of gravity conduits or breaks in suction lines caused 13 outbreaks, 9,540 cases of dysentery and 1,814 of typhoid fever. The use of vitrified tile pipe for gravity transmission of water took a heavy toll. This group included the classic Salem, O., epidemic, the Brigham, Utah, typhoid outbreak, and the Greenville, Ill., dysentery outbreak.

TABLE V

RELATIVE MAGNITUDE OF WATER-BORNE OUTBREAKS 1920-1929 INCLUSIVE

United States

Breaks in suction lines were responsible for 2 outbreaks at Grand Forks, N. D., and the well known Olean, N. Y., epidemic. In Canada, 3 outbreaks were due to the use of auxiliary intakes and 1, the Kingsville typhoid outbreak, was due to a break in the intake pipe.

The contamination of water in storage in reservoirs and cisterns caused 5 outbreaks in the United States and 3 in Canada. In 4 of those in the United States there were 1,269 cases of dysentery. The largest one was at Marseilles, Ill., where leakage from a polluted stream adjacent to a storage reservoir caused 700 cases; a second at Canton, Mo., resulted in 500 cases of dysentery, 42 of typhoid fever, and 3 deaths.

RELATIVE MAGNITUDE OF WATER-BORNE OUTBREAKS AND THEIR CONTRIBUTING CAUSES

To permit study of the relative importance of various contributing causes of water-borne outbreaks by their number and cases of typhoid fever and dysentery resulting, this information has been arranged statistically in Tables V and VI.

While the greatest number of outbreaks in the United States were due to drinking water from shallow wells, unprotected cross-connections and inadequate control over purification methods, however, account for the largest numbers of cases of typhoid fever and dysentery respectively. The public health importance of unprotected cross-connections is further emphasized by the fact that this rated second in causes for total outbreaks and fourth in dysentery cases. From these figures it might well be classed as the outstanding public health danger in water works operations.

Considering the number of persons affected, failures in purification methods lead the list; but in using this figure of 47,707 persons affected, it must be remembered that 45,000 of these were cases of dysentery in one outbreak in Detroit in 1926. Second in importance, as to total number of persons affected, is water in transmission through tile gravity conduits. This is a dangerous practice, and both water works and health officials should insist upon its discontinuance. The unprotected cross-connection hazard comes third in order of persons affected, and the use of water from shallow wells is fourth.

In Canada, polluted surface waters, inadequate control over purification methods, and unprotected cross-connections are the most important factors requiring the attention of health and water works officials.

Of the 47 states from which reports were received, 9 had no water-borne outbreaks. This does not mean that there was no typhoid fever in these states during this decade, but that there were no outbreaks of

TABLE VI

any magnitude in a single locality for the decade. They are: Arkansas, Colorado, Connecticut, Delaware, Florida, Louisiana, Massachusetts, New Hampshire, and Nevada.

Wyoming reports 609 cases and 139 deaths from typhoid fever for the decade. They were not classified as to cause and therefore could not be included in this statistical summary. It is reported that practically all of these were water-borne and occurred in Big Horn County due to drinking water from the Shoshoni River, on the watershed of which an increasing number of tourists have resided during summer months.

THE LARGEST WATER-BORNE OUTBREAKS

In Tables VII and VIII statistics are given of the 25 largest water-borne typhoid fever and dysentery outbreaks of the decade in the

United States and the 10 largest for Canada. It is interesting to note that 8 of the typhoid outbreaks in the United States and 3 of those in Canada had 200 cases or more each.

Each country had an epidemic of about 1,000 cases. That at Winona Lake, Ind., was due to a cross-connection with the water supply at a religious camp meeting place. The State Board of Health reports that practically all of the victims were out of town visitors, citizens in a large number of states being affected. The 1,000 reported cases probably do not include all which occurred, although the extent of this outbreak was thoroughly investigated.

The Cochrane, Ont., typhoid fever epidemic, with 935 cases and 70 deaths, was one of the most severe water-borne outbreaks in Canada's history. It was caused by sewage entering a lake from which the city water supply was obtained, owing to a change in water level of an adjacent lake into which the city discharged its sewage. Considering that the population of Cochrane was only 3,500, this is one of the most severe outbreaks on record.

The Salem, O., typhoid outbreak, as well as the one at Santa Ana,

82,734

$$\% \text{ of all Dysentery} = \frac{82,734}{83,995} = 98.6$$

Calif., were bitter lessons in public health control. The former was caused by sewage entering a break in a gravity conduit; the latter by sewage backing up in a drain from an air lift well allowing pollution to enter the top of the well.

Ten dysentery outbreaks included 1,000 or more cases. It is believed that the reporting of dysentery cases in connection with other typhoid outbreaks is far from complete. No dysentery cases were reported in the Canada statistics.

In both the Salem and Santa Ana outbreaks there was a large number of dysentery cases as well as typhoid fever, 7,000 and 10,000 respectively. The Detroit outbreak leads the dysentery list with 45,000 to 50,000 cases.

REPEAT OUTBREAKS FROM SAME CAUSE

There were 5 repeat outbreaks from the same cause, indicating lack of proper corrective measures. These were:

City	State	Year	Typhoid Fever		Dysentery	Cause
			Cases	Deaths	Cases	
Talledega	Alabama	1921	25+	—	—	Improper chlorination control
"	"	1923	17	—	—	" " "

DAMAGE SUITS RESULTING FROM WATER-BORNE OUTBREAKS

During the decade 1920–1929 considerable history was made in the courts both in the United States and Canada as to the responsibility of cities, private water companies and industries in regard to illness resulting from pollution of public water supplies. The trend of the courts is distinctly toward awarding substantial damages against those cities and companies subjecting the public to health hazards through carelessness. Among the more important suits were those at:

United States
Olean, New York
Albany, New York
Ogden, Utah
Everett, Washington
Fort Wayne, Indiana
City "A," Texas

Canada
Owen Sound, Ontario
Jordan, Ontario
Kingsville, Ontario

CONCLUSIONS

1. While the typhoid fever death rate in the United States and Canada has made a phenomenal drop since 1900, many large water-borne typhoid outbreaks have occurred during the last decade.

2. Special attention is needed for better control over the safety of water supplies in small cities, as 64.9 per cent of the outbreaks in the United States and 77.5 per cent of those in Canada occurred in those of 5,000 population and under.

3. A study of the causes of 282 outbreaks shows clearly the need for more attention on the part of water works and health officials to supervision and control over treatment processes, especially over disinfection where pollutorial loads on treatment plants are high or where chlorination is the only safeguard.

4. Over three-quarters of the water-borne illness reported in the United States during the decade 1920–1929, representing 40 per cent of the outbreaks, was due primarily not to pollution of the raw water at its source, but to defects in the system for collecting, treating, storing or distributing of the water for public consumption.

5. Unprotected cross-connections between polluted fire supplies and public water systems were the most important single cause contributing to water-borne outbreaks during the decade 1920–1929 and demand the most active attention of health and water works officials.

6. During the decade there were 5 repeat water-borne outbreaks in 1 city from the same cause, and repeat outbreaks in 4 from different causes.

7. The courts in both the United States and Canada are increasingly holding cities and water companies liable for heavy financial damages for illness resulting from pollution of public supplies.

Epidemiological Study of 383 Cases of Meningococcus Meningitis in the City of Milwaukee, 1927-1928 and 1929*

M. R. FRENCH, M. D., F. A. P. H. A.

Director, Bureau of Communicable Disease, Health Department, Milwaukee, Wis.

SOME communicable diseases such as smallpox, diphtheria, and typhoid fever can now be definitely prevented or controlled through the use of our present-day knowledge of medical science. Other communicable diseases, however, particularly meningococcus meningitis, appear now and then to take their toll of human lives. The methods of prevention or control have very little influence on the progress of this disease.

Meningococcus meningitis began to show an increase above its normal expectancy in Milwaukee, an industrial city of 575,000 population, in December, 1926. During the following 3 years, 1927, 1928 and 1929, it was prevalent in the city, and 383 definitely confirmed cases, with 208 deaths, occurred during this time.

There were 2 large epidemic waves. The first started in December, 1926, and reached its peak in April, 1927, fell to a fairly low point in August, but was still above its expectancy. The disease again increased somewhat in October and November, fell in December, and showed a small rise in March and April of 1928, then fell for the first time below its normal expectancy in August. The second began in October, 1928, reached its peak in March, 1929, and then during the following months dropped until September when it fell below its expectancy. In November and December it rose slightly, but in January, 1930, the disease fell below its norm, and during the past 9 months of 1930 has continued low. The wave of 1927 and 1928, with the smaller waves, continued for 19 months; and the second starting in October, 1928, continued for 12 months. There was a very definite seasonal incidence of these waves, which reached their peaks in the early spring months, March and April.

* Read before a Special Session on Meningitis of the Laboratory, Health Officers, and Epidemiology Sections of the American Public Health Association at the Fifty-ninth Annual Meeting at Fort Worth, Tex., October 27, 1930.

The cases of meningococcus meningitis, although somewhat scattered, were more prevalent in certain parts of the city. One area in the center of the city just west of the Milwaukee River, in a radius of 45 square blocks, had over 58 cases. This area contains a mixed population, and is commonly called "The League of All Nations," because there are at least 20 different races and nationalities in that locality. It is also a very congested and very poor district. East of this area, across the river, there was another group of cases composed largely of Italians. In the lower part of the city was the third group, made up very largely of the Polish. Forty-three of the cases were persons living in neighboring communities, who were brought to local hospitals for treatment.

The ages of the persons with meningococcus meningitis ranged from a few days to 60 years. The largest number of cases was in the preschool age group, 1 to 5 years, followed closely by the school groups, 6 to 10, and 11 to 15. These groups were followed by babies under 1 year, and next were the adults, with a decrease in cases as the age increased (Figure II).

Almost twice as many males had meningococcus meningitis as females. There were 235 males compared to 148 females. This larger proportion of males to females was evident in all of the age

FIGURE I

FIGURE II

groups with the exception of the groups 41 to 45 and 51 to 55, in which the females were in the larger proportion (Figure III).

Eighteen different races or nationalities and one unknown group were represented in the 383 cases. The nationality of these groups portrays country of origin, and not necessarily country of birth. The American group was a mixed one in which the parentage was made up of many different nationalities. The American, Polish and German nationalities lead in the number of cases, followed by the Negro and Jewish races, then by the other nationalities of Europe, Ireland, and Mexico (Figure IV).

The Negro race, 4th in number of cases, has during the past few years shown a marked increase in Milwaukee. There were only 2,000 in the city according to the 1920 census, while in 1927, according to a report from the Milwaukee Urban League, there were between 8,000 to 10,000. This increase was very largely due to the influx from the southern states; and the Negro race coming from a mild climate to a northern one, and living in unfamiliar conditions, was found to be rather susceptible to this disease.

FIGURE III

The schools played no part in the spread of meningococcus meningitis, although a number of cases were among school children. One case was found in each of 52 schools; 2 cases each in 10; 3 cases each in 7; 4 cases each in 2; while in 1 there were 5 cases. However, there was no relationship between these cases for they developed at different

FIGURE IV

times and there was no association or contact between them, as they were children in different classes.

The common symptoms complained of were largely those usually found at the beginning of a communicable disease, with some localization of infection in the central nervous system. The most common symptoms found in the 383 cases were fever accompanied by vomiting, headache of a very persistent and severe type, restlessness and some retraction of the head, drowsiness from which it was difficult to arouse the patient, and constipation. In some cases the patient complained of pain in the back on bending the body backwards. A sore throat or a cold very frequently ushered in the disease, while diarrhea and tenderness of the neck on bending the head back were present in a number of cases.

FIGURE V

Meningococcus meningitis had a rather high fatality, which was about the same for each of the 3 years.

In 1927 there were 92 deaths and 79 recoveries, a case fatality of 53 per cent; in 1928, 49 deaths and 41 recoveries, a case fatality of 53 per cent; in 1929, 67 deaths and 55 recoveries, a total for the 3 years of 208 deaths and 175 recoveries, a case fatality of 54 per cent.

The case fatality varied somewhat in the different age groups, the highest being in the age groups 41 to 45, and 46 to 50, in which all of the 15 cases died, a case fatality of 100 per cent.

Next came the babies under 1 year, with a case fatality of 84 per cent; followed very closely by the groups 51 to 55, and 56 to 60, in which the case fatality was over 80 per cent.

The groups with a case fatality of 60 per cent and over were adults 26 to 30, 31 to 35, 36 to 40; followed by the age group 16 to 20, with a case fatality of 57 per cent; and next those of preschool age 1 to 5 with a case fatality of 40 per cent. The group with the lowest case fatality, 36 per cent, was that of 11 to 15 years of age.

The largest proportion of cases were treated in local hospitals, only a few being treated at home. One hundred and sixty-one cases were cared for in the Municipal Contagious Disease Hospital, known as South View Isolation, where 61 died and 100 recovered, a case fatality of 37 per cent. In 10 other hospitals in the city 152 cases were treated, 95 died and 62 recovered, a case fatality of 62 per cent; while in the homes where 70 cases were treated, 52 died and 18 recovered, a case fatality of 74 per cent. All of these cases in the various hospitals and homes represent different types of infection, from those who were overwhelmed and died within a short time, to those who had some resistance and fought the disease for a certain length of time without serum treatment. The Municipal South View Isolation Hospital, which had the lowest case fatality rate, used routinely the cisternal puncture in treatment with the other methods, and found it to be safe and efficient.

The first few days of illness were the ones of greatest danger for the life of the patients, for 60 per cent of all deaths occurred during the first 6 days of illness. The largest number of deaths occurred on the 3d day, followed closely by the 1st, 6th, 2d, 4th and 5th days. Deaths continued to occur, however, during the following days, decreasing as the number of days of illness increased.

No recoveries were reported until the 12th day of illness, and from that time on through the 35th day over 77 per cent of all recoveries had taken place. The largest number of recoveries were from the 21st to the 26th days of illness. However, recoveries continued to be reported for as long as 60 days and over from date of onset (Figure VI).

A large number of adults and children were exposed, but did not develop it. Eight hundred and forty adults and 690 children contacts, under 17 years of age, were closely associated with persons who had meningococcus meningitis, and showed no symptoms of this disease. Three hundred and forty-six persons developed meningococcus meningitis and no further cases occurred among the immediate contacts or associates in the family; while in 17 different families there were 2 or more cases in each, or a total of 37 multiple cases.

FIGURE VI

In 3 of these families, Nos. 4, 15, and 16, where multiple cases occurred, there were 3 cases each, while in the other 14 there were only 2 cases. In all of the homes with the exception of the first 3 there was an interval of a few days between the onset of the first case and the others. In the first 3 the dates of onset of the 1st and 2d cases were the same.

Information concerning family No. 17 is somewhat uncertain because both cases, a husband and wife, were taken out of a burning building in a semi-conscious condition to the Emergency Hospital where it was found that they had meningococcus meningitis, and they died before complete information could be obtained.

As a rule the older persons in the family developed the disease first, with the exception of families Nos. 14, 16, and 17 (unknown). This was especially noticeable in family No. 5 where the mother, the 1st case, developed the disease 3 days before her 19 months old baby came down. Also, in family No. 6 where the father, 36 years old, developed the disease 7 days before his 10 year old son, both slept together just prior to the onset of their illness. In family No. 7 the 25 year old uncle developed the disease 3 days before his 10 year old niece.

The interval between the onset of these multiple cases in the homes varied from the same day to $8\frac{1}{2}$ months. Eight multiple cases developed the disease on the same day in their respective families, indicating a common source of infection in the home; 20 developed within

MENINGOCOCCUS MENINGITIS
 37 MULTIPLE CASES BY FAMILIES, TIME OF ONSET AND AGE
 1927-1928-1929
 CITY OF MILWAUKEE

1 to 8 days; 3 developed within $2\frac{1}{2}$ months; 2 cases in $8\frac{1}{2}$ months; and the interval for 2 was unknown.

All of the contacts with cases of meningococcus meningitis had postnasal cultures taken to detect possible carriers. The percentage of carriers found varied from an average per month of less than 1 to as high as 30 positive.

All carriers were isolated until two consecutive negative cultures were obtained, and as a rule they cleared up rather quickly; 12 days being the longest time that any was held. The culturing and isolation of these carriers seemed to have little or no influence in preventing the spread of this disease.

SUMMARY

Meningococcus meningitis was prevalent in the City of Milwaukee for 3 years, with 383 cases, resulting in 208 deaths. The cases, although scattered, were more prevalent in certain congested parts of the city, and there was a high seasonal incidence in the early spring months of March and April. The ages varied from less than 1 year to 60 years, the highest proportion being in the preschool age group under 5 years, and there was a larger proportion of males than females. The American, German and Polish nationalities lead all others in number of cases.

The schools played no part in the spread of this disease, although a number of school children had it.

The morbidity, or number of cases that developed, was not influenced by the culturing or isolation of carriers. The case fatality rate, however, was influenced by the age of the patient, being highest in the age group 41 to 50, and under 1 year. It was also influenced by the kind of treatment given, being highest in those treated in the homes and lowest in the hospital where the cisternal method was used routinely. The largest number of deaths occurred during the first few days of illness, and the patients who lived through the first 6 days had a fair chance of recovery.

The possibility of intimate contacts developing meningococcus meningitis was very slight, for less than 1 per cent of those exposed developed the disease. The older ones in the family, where there were multiple cases, as a rule, developed the infection first, and in no instance did an adult develop the disease after a child in the family.

Exit the Milkmaid

"Where are you going, my pretty maid?"

"To look at the merry-go-round," she said.

"Will you ride on it with me, my pretty maid?"

"Oh, no, sir; it's just for the cows," she said.

In some such fashion the old nursery rhyme must be remodeled to celebrate the machine's latest triumph—elimination from the scene of the milkmaid, with her wooden pail, three-legged stool and fly swatter. The new rotolactor, as installed at a dairy near Plainsboro, N. J., seems certain to make that romantic rural creature a constant reader of the "Help Wanted" columns. The device is nothing more than a slow-motion merry-go-round, without music, on which the cows, 50 of them, ride while a milking machine does the milkmaid's former duty.

First, however, Bossy gets a bath from a hose; then she is dried by hot air, and finally she is milked while riding gracefully around the barn, with another cow waiting to take her place when the circuit is completed. True, the milking is done under more hygienic auspices, and in less time than it would take the milkmaid to remove Bossy's tail from the bucket. But the passing of a picturesque calling is to be lamented, particularly when other feminine fields are overcrowded with too many permanent wavers, Hollywood aspirants and woman stunt flyers.—*St. Louis Post-Dispatch*, Jan. 21, 1931.

An Epidemic of Cerebrospinal Meningitis in Saginaw, Mich.*

WILLIAM H. PICKETT, M. D., F. A. P. H. A.

*Director, Bureau of Rural Hygiene, State Department of Health, Lansing, Mich.
(Formerly, Health Officer of Saginaw)*

SAGINAW is a city of approximately 85,000 population, composed of white, brown, and black races. It was a great lumbering center in its earliest days, but during the past decade has developed into an industrial and agricultural center. On account of its extensive industrial development, laborers have moved into the city from all parts of the United States, Canada, and Mexico.

The first knowledge that the local Health Department had of the presence of meningitis in Saginaw was on February 13, 1929, when it was accidentally learned that there were 5 cases in one hospital and 2 in another. This number of any type of meningitis cases demands an immediate investigation, which was made, and the 7 cases were promptly segregated in the two public hospitals. All close contacts were cultured for possible carriers.

Owing to the seriousness of this disease, the extreme restlessness of the patients, and the difficult treatment necessary, it was determined to hospitalize all cases if possible. Saginaw did not have a contagious disease hospital when the epidemic began and only after a humanitarian plea was made at a joint meeting of the boards of the two institutions mentioned was it possible to obtain adequate hospitalization for the cases which subsequently developed.

All culturing of cases was done by the local laboratory. This policy was adopted for three reasons: (1) it would cost less than the employment of additional personnel who would be compelled to have special laboratory training; (2) the meningococcus does not live at room temperature long enough to get to the laboratory with swabs, without incubation at body temperature; (3) the swabs are best taken by a person having a thorough knowledge of the peculiarities and characteristics of these germs, especially as to their habitat in nature or

* Read before a Special Session of the Laboratory, Epidemiology, and Health Officers Section of the American Public Health Association at the Fifty-ninth Annual Meeting at Fort Worth, Tex., October 27, 1930.

location in the posterior wall of the nasopharynx, and an understanding of the measures employed to guard against contamination of the swab by saliva.

A large epidemiological chart of all cases was kept in the Health Department office, on which the following information was recorded: name of patient, number of case, hospital or home case, death or recovery, exposure to healthy carriers, residence address, milk supply, color, age, sex, type and place of occupation, types and places of occupation of other members of the family, school and grade, date reported, attendance at dances, churches, theaters, Sunday schools, bathing pools, parties or other public or private gatherings, during 14 days prior to illness. With this chart before him, the health officer was enabled to detect a common factor in any 2 or more cases and be guided in his actions.

MANAGEMENT OF CASES

Cases or suspected cases were hospitalized promptly. Since the treatment is heroic and difficult to administer in the home, hospitalization was insisted upon. This enabled the physicians to render maximum treatment with minimum danger to the patient. No patient was released from the hospital or home until 2 successive negative cultures taken from swabs of the nasopharynx, 24 hours apart, were reported by the laboratory, and not until after the 14th day from the onset of the disease under any circumstances.

All cases except 11 were hospitalized, and of these 11 who refused hospitalization 7 died. These families were rigidly quarantined for a minimum of 14 days except the breadwinners, who were released after the first negative swab and allowed to reside elsewhere so as to carry on their occupations.

Thorough cleaning, disinfection, exposure to fresh air, and sunlight were required for all homes when cases were removed or after recovery.

The field investigations of the cases failed to show contact between known cases or a common source of infection. Moreover, since no relationship was established as to sex, color, age, milk supply, occupation, residence, habits, etc., it was postulated that the disease was spread by healthy carriers.

MANAGEMENT OF CONTACTS

The indiscriminate culturing of groups of casual or transient contacts was not done except when as many as 2 cases occurred among a small group, and then only after the group survey indicated the necessity. At no time during the epidemic did secondary cases occur out-

side of a few large families where the homes were small and the living conditions crowded and intimate.

Contacts were taken by their own private conveyances or carried at county expense to the laboratory for culturing, and then returned home to remain in quarantine until negative reports were received for each of the 2 separate 24-hour cultures. If the reports showed that there were no carriers found among any of the close contacts, all bread-winners were promptly released, but all school children or other members of the families were kept at home for 7 days irrespective of the negative laboratory reports. If a carrier was found among the contacts, he was placed under placarded isolation in a room alone, with separate eating, drinking, toilet and sleeping facilities until 2 successive negative cultures were obtained by the laboratory after the 7th day. No carriers were kept in isolation longer than 14 days, and those showing a positive culture were carefully instructed upon release.

GENERAL DATA

This epidemic resulted in 264 cases and 85 deaths. The cost to the county for proper care of these cases and contacts was \$60,000. This sum is indicative of the fact that a majority of the cases were among families of the lower economic group.

A very small minority of the population, including 1 physician and

Incidence of Cases and Deaths by weeks

1 dentist, during the first few weeks listened with over-anxious ears to greatly exaggerated reports and caused the Health Department no small amount of unnecessary trouble as well as extra work in proving the rumors untrue. These few hysterical persons did not seek first hand information, and except for the medical profession and the newspapers, who were kept truthfully informed, might have caused more damage to business, school attendance, etc., than even a much more serious epidemic could have done.

The State Health Department was asked to send a consultant on 3 or 4 different occasions, and on each visit the local Health Department as well as the public was advised that all was being done that could be done to produce the best possible results.

Figure I shows how prominent a part epidemic meningitis played as a cause of death among the nine leading diseases in Saginaw during the year July 1, 1928, to June 30, 1929.

Figure II shows cases and deaths from epidemic meningitis by weeks from February 11, 1929, to August 27, 1929, inclusive.

It will be noticed that the peak of the epidemic appeared early during the sixth week, and from that time on there was a more or less steady decline in cases and deaths.

DISTRIBUTION OF CASES

Geographical—Every ward had at least 2 cases and in the 1st and 21st the cases greatly outnumbered those in any others. In these two wards, the population is composed of a mixture of white, colored and Mexican families and there is much crowding as well as poor sanitation. It is not possible to learn the population by wards at this time, so a word picture instead of actual figures must be used. There is a very large industry located in the midst of the 1st and the 21st wards, which during the 18 months preceding the epidemic doubled its capacity, and as a result many laborers came from all parts of the United States and Mexico, many of them locating as near the plant as possible in houses which were already full. Since there were no vacant houses, there was, and is yet, only a partial relief to the crowded condition in these homes.

Racial—Figure III shows cases and deaths distributed according to color.

CITY OF SAGINAW
EPIDEMIC MENINGITIS
Cases and Deaths by Race 1929

FIGURE III

CASES AND DEATHS BY RACE

White cases	number	197	Deaths	59	Fatality	per cent	30
Negro	"	32	"	13	"	"	40
Mexican	"	35	"	15	"	"	43

The proportion of Negroes and Mexicans in the general population of Saginaw is not known, but on the basis of their estimated proportion the number of cases of meningitis was higher among these two groups than among the white population.

The colored and Mexican patients received the same quantity and quality of hospital and professional treatment as did the white; consequently, less resistance to the disease is suspected as being the factor responsible for the higher fatality. Change of climate, crowded and unhygienic general living conditions and poor personal hygiene were no doubt important contributing factors.

It may be of interest to note that of the 32 Negro cases 26 came from rooming houses and that only 11 carriers were found among the close contacts. Among the 35 Mexican cases, 29 came from rooming houses or homes with more than 1 family living in them and 16 carriers were found among the contacts.

Occupational—The occupational distribution shows that among 66 industrial cases 14 different callings were represented, with the greatest number of cases coming from the very large industry located in wards 1 and 21.

Housewives developed the disease and in each instance the home work had been done by the patient.

School—Among 61 cases occurring among school children, 31 schools were represented, and only in 2 instances did as many as 2 cases occur in 1 schoolroom. The children in the 2 rooms were cultured and no carriers found, but adult carriers were found at home in 1 of the 2 instances.

Source of Milk Supply—The distribution of cases according to milk supplies is interesting in that for the 264 cases there were 26 separate sources. Like every other group of possible sources, milk was ruled out, leaving the healthy carrier as the only possible source.

AGE GROUPS OF CASES, DEATHS AND CARRIERS

Figure IV shows the cases, deaths and carriers distributed according to age groups in 5 year periods.

It is at once noticed that cases and deaths are highest among the young—from birth to 4 years—and are lowest among the school age groups. It is more interesting to note the excess of carriers found among adults over those in the very young or school age groups.

There were approximately 500 cultures taken among the close contacts of which 73, or 14 per cent, were positive. None of the 73 carriers had any symptoms of the disease. About 4 per cent remained carriers after the 14th day; all others gave 2 negative cultures by the 10th day.

FIGURE IV

SECONDARY CASES AND RECOVERED CASES

In 2 instances, there were 3 cases in a family, and in 9, 2 cases in a family. All other cases came from homes or boarding houses where only 1 case per house developed.

Following is a summary of defects, classified more or less according to parts of the bodies affected, determined by a survey of physical conditions among recovered cases, 2 to 7 months following discharge from quarantine.

Many of these so-called recovered cases have several of the above conditions. In 2 instances, after the patients had made apparently complete clinical recoveries, they suffered relapses. Symptoms appeared exactly like those of the first attack 2 months previously. No meningococci were isolated during the second attack from either the spinal fluid or the throats.

SUMMARY OF DEFECTS 2 TO 7 MONTHS AFTER DISCHARGE

Well and in good health	66	Motion of arms affected	4
Defective hearing	24	Markedly underweight	3
Defective vision	18	Defective speech	3
Very nervous	15	Stiffness in muscles of neck	2
Tire easily and on part time work	13	Enlargement of joints	2
Pain in back	12	Persistent sore spot on spine	1
Stiffness in lower limbs	11	Nephritis	1
Instability of mind	6	Scoliosis	1
Severe headaches	4		
Returned to hospital second time	4	Under physician's care when visited	27

SUMMARY

Experience gained during the Saginaw epidemic of cerebrospinal meningitis indicates that the following measures are of great importance:

1. Immediate hospitalization of cases
2. Immediate use of serum for cases only
3. Quarantine and multiple culturing of all cases
4. Multiple culturing of close contacts only
5. Keeping the public truthfully informed as to the
 - a. progress of the epidemic
 - b. nature of the disease
 - c. precautions necessary

Futility

HE brushed his teeth twice a day with a nationally advertised toothpaste, reports Louis L. Morris, editor of the *Hartwell, Ga., Sun*. The doctor examined him twice a year. He wore his rubbers when it rained. He slept with the windows open. He stuck to a diet with plenty of fresh vegetables. He relinquished his tonsils and traded in several worn out glands. He golfed, but never more than 18 holes at a time. He got at least 8 hours sleep every night. He never smoked, drank or lost his temper. He did his daily dozen daily. He was all set to live to be a hundred.

The funeral will be held next Wednesday. He is survived by 18 specialists, 4 health institutes, 6 gymnasiums and numerous manufacturers of health foods and antiseptics.

He had forgotten about trains at the grade crossings.—*Western Hospital Review*, Jan., 1931.

Experience of the Meningitis Division of the New York Department of Health*

JOSEPHINE B. NEAL, M. D.

Meningitis Division, Department of Health, New York, N. Y.

THE Meningitis Division of the Department of Health of New York City was established by William H. Park, M.D., in 1910. Its original purpose was to provide a staff of physicians trained in the diagnosis and treatment of meningococcus meningitis. The services of this staff are available to the physicians of New York City and cases are seen only in consultation. The establishment of this division was advisable because the successful diagnosis and treatment of meningococcus meningitis calls for no small degree of experience.

No general rules in regard to the administration of serum can be followed routinely; each case must be treated individually. Cases are seen only in consultation with the family physician, as we wish to co-operate, not to compete, with the general practitioner, and also as the family is better satisfied if its own physician is present.

As time has passed, the scope of the work has expanded to include other forms of meningitis, infantile paralysis, epidemic encephalitis and other acute diseases of the central nervous system. We also see many patients suffering from various diseases in which meningeal symptoms are present without a real infection of the central nervous system.

Laboratory facilities are provided for the examination not only of the spinal fluids of our own cases but also of those sent to us by physicians who are taking care of their patients without our coöperation.

The physicians of the staff of the Meningitis Division are available at any time. Meningitis, poliomyelitis and epidemic encephalitis are reportable to the Health Department. The reports are forwarded to our office. The physicians in charge of the cases are called by us to learn if consultation is desired. At present many physicians call us

* Read before a Special Session of the Laboratory, Epidemiology, and Health Officers Sections of the American Public Health Association at the Fifty-ninth Annual Meeting at Fort Worth, Tex., October 27, 1930.

directly. One might think that our work has a very limited field. As a fact, the scope of diseases to be diagnosed is a large one. A partial list of diagnoses made during the last 3 years includes the following diseases in addition to the various forms of meningitis, poliomyelitis and epidemic encephalitis: acute miliary tuberculosis, arsenical poisoning, anthrax, alcoholic neuritis, pernicious anemia, brain tumor, brain abscess, brachial palsy with cerebral hemorrhage, concussion of the brain, cerebral congestion with pertussis, chronic inflammatory arthritis, cerebral hemorrhage, cerebral embolism, chorea, cerebrospinal syphilis, dislocated atlas, diabetes, dementia praecox, endocrine imbalance, epilepsy, erysipelas, erythema nodosum, sarcoma of the spine, exacerbation of a chronic nephritis, early diphtheritic paralysis, fibrinous pleurisy, follicular tonsillitis, fracture of the skull, glandular fever, hemorrhage of the spinal cord, hydrocephalus, hysteria, influenza, intraventricular hemorrhage, lead poisoning, Landry's paralysis, meningism with pneumonia, scarlet fever, enteritis, acidosis, otitis media, food allergy, malnutrition, typhoid fever and colitis; meningitis sympathica or serous meningitis with sinusitis, meningeal hemorrhage with bacterial endocarditis, multiple sclerosis, mastoiditis, myelitis, multiple neuritis, Mongolian idiocy, neurosis, neurasthenia, osteomyelitis, pyelitis, phlebitis, progressive muscular atrophy, paralysis following antirabic treatment, parotitis, post-diphtheritic paralysis, post-influenzal asthenia, rheumatism and pericarditis with embolism, retropharyngeal abscess, rickets, Schilder's disease, spontaneous meningeal hemorrhage, subacute spondylitis, status epilepticus, scurvy, spina-bifida, sinus thrombosis, septicemia, typhus fever, tuberculous adenitis, trigeminal neuralgia, transverse myelitis, toxemia of pregnancy, trichinosis, tetany, varicella, whooping cough, methyl alcohol poisoning, encephalitis associated with scarlet fever, pneumonia, bronchial pneumonia, measles and vaccination.

Many of our cases and groups of cases present interesting problems but it will be necessary to limit this discussion almost exclusively to meningococcus meningitis.

Meningococcus meningitis may be divided as follows:

1. Acute forms—

- (a) Ordinary acute forms of greatly varying degrees of severity, in which the patient is well on the road to recovery or is dead within 10 days to 2 weeks
- (b) Fulminating, in which death occurs within 72 hours
- (c) Septicemic type, in which the septicemia is a more striking feature than the meningitis

2. Chronic forms—

- (a) Ordinary chronic form in which the disease lasts 3 weeks or more before there is a decisive change for the better or worse
- (b) Relapsing form
- (c) Form in which the process becomes walled off either in the ventricles producing a basilar meningitis, or in pockets forming the encysted or loculated meningitis

The clinical course of the disease depends to no small degree upon the age of the patient. It is especially severe in infants and in adults over 30.

The space allotted to this paper does not permit a discussion of the symptomatology of all these forms of meningitis. In the ordinary acute form of meningitis, which is the most common, the onset is sudden with headache, vomiting, fever and sometimes chills. Within 24 to 36 hours stiffness of the neck and a positive Kernig and Brudzinski usually develop. A Babinski may or may not be present. A hemorrhagic rash is found in a varying percentage of cases. This usually appears very early in the disease. Petechiae are most common but the rash may appear as macular or purpuric spots. In the great majority of cases it begins to fade in 1 to 3 days. Herpes is occasionally present. In the early stages superficial and deep reflexes are usually exaggerated. As the disease progresses these become less marked and may be lost entirely. They are not infrequently unequal, especially in the later stages. Early the pupils are usually equal and react to light and accommodation; later they often become fixed and may be unequal. Photophobia is quite common in the early stages. There is usually constipation in older children and adults. The temperature is irregular in type but does not show the wide variation of the usual septic temperature.

At the onset of the disease the pulse is generally a little slower than the elevation of the temperature would indicate; in the later stages it becomes more nearly in proportion to the temperature. The respiration is not significant early; late in unfavorable cases Cheyne-Stokes respiration often occurs. The mental condition shows a wide degree of variation. In mild cases the mentality may be normal throughout. In more severe forms there is marked irritability, delirium, apathy or stupor.

While a bacteremia is undoubtedly present early in practically all cases, the organisms have a predilection for the meninges and speedily localize there. In the septicemic type of meningitis, however, there is usually an invasion of the blood stream for several days or even weeks before a meningitis develops, and the septicemia may continue

after the development of the meningitis. In other cases the meningitis develops early and the septicemia and the meningitis continue together. In still other cases there is a prolonged meningococcemia without the development of the meningitis. These are comparatively rare.

In very young children the early signs and symptoms of meningitis indicate a disturbance of the gastrointestinal rather than of the central nervous system. The disease begins rather abruptly, often with vomiting, almost invariably with greenish slimy stools, irregular fever, and irritability. The fontanelle practically always shows increased pressure. The child does not respond to the ordinary methods of treatment for gastroenteritis, but it is not until the disease is fairly well advanced that stiffness of the neck, opisthotonos and changes in the reflexes develop. The case therefore is usually diagnosed and the serum treatment is begun late in the disease. It is for this reason, I believe, that the mortality in the first year of life is so high. Our mortality has been about 45 per cent. Debré said: "In times of epidemic think of meningitis and do a lumbar puncture on every infant sick without apparent cause." It is even more important in our opinion to do this when there is no epidemic.

UNUSUAL FORMS MENINGITIS

Whenever a patient shows signs of meningeal irritation, there should be no delay in doing a lumbar puncture. It is only by the examination of the spinal fluid that a definite diagnosis can be made. The symptomatology of all forms of purulent meningitis are so similar that the bacteriological examination of the spinal fluid is essential for the diagnosis. Early cases of poliomyelitis often present a picture not unlike that of early meningitis. The same is true of meningism with a variety of diseases. In the case of meningism, the relief of the increased intracranial pressure is of sufficient therapeutic value to warrant a lumbar puncture, in addition to its value in diagnosis.

FIGURE I

Figure I shows the distribution by age and etiology of more than 2,000 cases of meningitis. During the period in which these cases have been collected, nearly 20 years, there has been no severe epidemic in New York City. In 1917 and 1918, there was a sharp increase in the number of cases, and in 1928-1929, there was an epidemic of rather mild proportions. It shows also that meningitis of all forms is essentially a disease of childhood, and in the case of meningococcus meningitis, by far the largest number of cases occurs in the first year of life. Of course in times of war there are epidemics of meningitis among the young adults collected in the army camps.

In tuberculous meningitis the greatest number of cases occurs in the second year of life. In most instances of the other forms of purulent meningitis, the disease is probably secondary to a focus of infection elsewhere in the body, but it is sometimes difficult or impossible to locate it by clinical examination.

Figure II shows the seasonal distribution of our cases of meningococcus meningitis over a period of 20 years. It will be seen that by far the larger number of cases occurs in the first 6 months of the year. The incidence is

FIGURE II

somewhat larger among males than females. Of 1,007 cases, there were 584 males and 423 females. Meningitis is a disease to which there is apparently a high natural immunity. In our experience, there have been only 24 instances in which there was more than 1 case in a family, or a clear history of exposure. Of these, 10 occurred in 1916, 1917, 1918 and 1919, and 10 in 1928-1929. The reason for this immunity is problematical, but it may be noted that it apparently exists also in the case of poliomyelitis and epidemic encephalitis. Unfortunately, there is no test for this immunity as there is for scarlet fever and diphtheria.

The spinal fluid in meningococcus meningitis is practically always increased in pressure and amount unless there is blocking, and it shows a varying degree of turbidity. Very early in the disease or in the fulminating type, the fluid may show very little cellular reaction. In

the fulminating type there may be enormous numbers of organisms with a nearly clear fluid. As the disease progresses, the number of cells is greatly increased, with polymorphonuclears of 80 per cent or more. The actual cell count is of relatively little value. The number of cells may vary greatly in different portions of the spinal fluid and a high cell count has by no means an unfavorable prognosis.

In examining the spinal fluid the specimen should be centrifuged and smears and cultures made from the sediment. The smears should always be stained by the Gram method. A tentative diagnosis only should be made from the stained specimen, as the Gram positive organisms in other forms of meningitis may decolorize readily in some instances. Cultures should be made on a variety of mediums. Miss Gosling, of our laboratory, has found that a semi-solid medium with 1 per cent glucose, 0.25 to 0.5 per cent agar in beef broth, pH 7.2 to 7.4, is the most suitable, both for isolating the meningococcus and preserving the culture.

As the patient improves, the organisms become more and more intracellular and decrease in number. The protein is increased in varying amounts; the sugar may be normal very early in the disease, but as the disease progresses it practically always is decreased and may become entirely absent. As improvement begins, the protein content usually decreases and the sugar content increases—the latter we consider an important prognostic sign. In some instances it has been noted that a decrease in sugar has preceded the return of organisms when a relapse was about to occur. The identification of the meningococcus is most surely made by the fermentation reactions. It ferments glucose and maltose. A slide agglutination with the anti-meningitis serum is also of value. It is well known that the meningococcus is divided into different types, but they are by no means so clear cut and definite as in the case of the pneumococcus.

During the recent outbreak in New York City, most of the strains fell into Gordon Type I, but there was a good deal of cross agglutination with Type III. It may be recalled that in his original work Nicolle described a Type A as equivalent to the Gordon I and III. The different groupings that have been described by various workers serve to emphasize the difficulty of exactly classifying the various strains. In sporadic cases many cultures are found that fail to fall into any group.

Antimeningococcus serum has been accepted in the treatment of meningitis for about 23 years, and for more than 20 years its use has been very general. It seems a little strange that in spite of this long period there should still be so much difference of opinion in regard to

its proper administration with respect to route, frequency and amount. There are several reasons why this is so. One reason is no doubt the fact that at times serum of poor quality has been used, and in an attempt to save life it has been given in large and frequent doses when a more conservative treatment had been ineffective. When this more intensive treatment also failed, the physician knew little more than before in regard to the relative merits of the two methods. Another reason is, no doubt, that the type of the disease has differed quite markedly in different outbreaks. In certain outbreaks the septicemic form of the disease has been very common. In perhaps the majority of cases, this form is relatively rare. A third reason probably lies in the fact already stated, that each case of meningitis must be studied and treated more or less on its own merits. One can therefore gain a comprehensive view of the disease only after quite extensive experience. It is a great mistake to draw conclusions from the observation of only a few cases.

Our opinion in regard to the treatment of meningitis is based on an experience of 20 years with more than 1,000 cases. During this time we have compared our results with those obtained in institutions where much more radical methods of therapy were employed. Our method is usually as follows: whenever a lumbar puncture yields a cloudy or hazy fluid, antimeningococcic serum warmed to body temperature is immediately administered by gravity. Further serum treatment will depend on the cultural examination of the fluid, but all cases of purulent meningitis are treated as being of the meningococcus type until they are proved to be caused by some other organism. Intraspinal administrations of serum are continued about every 24 hours until at least two successive specimens of the fluid show no organisms by smear or culture.

The dose of serum is usually 20 c.c. if as much or more fluid has been obtained. If the amount of fluid withdrawn is great and the serum runs in easily by gravity, without untoward symptoms on the part of the patient, 30 to 40 c.c. may sometimes be administered. On the other hand, in certain instances when only a small quantity of fluid is obtained we may inject more than the amount of fluid withdrawn provided the serum runs in easily and no unfavorable symptoms result. It is desirable to drain the subarachnoid space as completely as possible before injecting serum, but if the fluid is under greatly increased pressure, care should be taken to withdraw it slowly. Using this precaution, 50 to 60 c.c. or more of fluid may be safely withdrawn. If headache develops during the removal of the fluid, it usually quickly disappears when the serum is injected. Almost the only condition

under which we inject serum oftener than once in 24 hours is when the fluid is under so greatly increased pressure that a puncture at more frequent intervals seems indicated to relieve it. This rarely occurs.

Some physicians have recommended graduated doses of serum for young children, depending rather arbitrarily on the age. We have not found this necessary. We depend rather on the amount of fluid withdrawn and the ease with which the serum runs in by gravity in determining the size of the dose, but it is necessary to exercise more than ordinary care in removing fluid and injecting serum in young babies.

It is rarely safe to give fewer than 4 doses of serum. A case of average severity will require perhaps from 6 to 8 doses, and cases are occasionally seen where 20 or more are necessary before the fluid becomes sterile. As stated, the serum treatment is continued until 2 successive fluids are free from organisms. This is by far the most important indication for stopping treatment. Another indication, of less value, is the return to normal of the spinal fluid sugar. The cell count of the spinal fluid is, by itself, of comparatively little value. When two sterile spinal fluids have been obtained it is usually safe to stop the serum treatment, temporarily at least. It is often necessary to do several lumbar punctures during convalescence for the relief of pressure, and these fluids should be carefully examined and cultured, as the return of organisms would indicate additional serum treatment. I have emphasized the laboratory tests as a guide to the administration of the serum, as it is rare indeed that the clinical picture is not accurately reflected or even predicted by the changes in the spinal fluid. If, however, the symptoms do not improve after the fluid becomes sterile, and the serum has been temporarily discontinued, it is well to resume the injections, as they may be due to a localized meningitis with adhesions which may be favorably influenced by the continued use of the serum.

If signs of blocking develop, recourse should be had to ventricular or cisternal punctures and the administration of serum by these routes. In babies where the fontanelle is still open, ventricular puncture is to be preferred to cisternal as it is less dangerous and more certain of success, since the block is quite as likely to be above the cistern as below it. We have occasionally encountered cases where little or no fluid has been obtained by lumbar puncture and yet serum has run in easily by gravity, and there have not been signs of increased pressure. Several such cases have made satisfactory recoveries without resorting to ventricular or cisternal punctures.

We are, perhaps, more conservative than many in doing ventricular or cisternal punctures. I have never seen any immediate harm follow

a ventricular puncture. On the other hand, comparatively few babies where this treatment has been necessary have recovered. I do not believe that we know at present what may be the after effects of the repeated trauma to the brain tissue. As regards cisternal punctures I do know that death has occasionally followed promptly, due to hemorrhage. It seems unfortunate that these fatalities are not reported, as we not infrequently read accounts of large series of cases without accident written by physicians using this technic in patients with syphilis of the central nervous system. The dangers are much greater, I believe, when there is an active inflammatory process with layers of adhesions in the neighborhood of the cistern, as is likely to be the case in meningitis. Cisternal punctures should be attempted only by those who have had adequate practice on the cadaver.

In regard to the intravenous or intramuscular injection of serum, we believe that this is indicated only in cases of meningococcus septicemia without meningitis, or in those cases of meningitis which show a prolonged invasion of the blood stream by the organisms as indicated by repeated positive blood cultures or a rash that shows a tendency to persist or to recur. While it is probable that in practically all cases of meningitis there is an invasion of the blood stream early in the disease, we think that in the very great majority of cases this invasion is transitory and that injections of serum other than intraspinally are unnecessary. In some instances this has been proved by blood culture and in many more it has been very definitely established by the rapid fading of the rash and the clinical improvement of the patient. The intravenous administration of serum is not without danger, as a severe or fatal reaction occasionally follows. Several such instances have been brought to our attention. Certainly patients tolerate serum much better by the intraspinal than by the intravenous route.

In cases that run a chronic course and in the occasional case that does not tolerate serum, we have used an autogenous vaccine, often with apparently good results. We have given the vaccine both subcutaneously and intraspinally. We are not prepared to claim too much for it as in some cases no benefit has followed its use. My colleague, Dr. Appelbaum, has recently reported a case in which an autogenous vaccine was administered both intraspinally and subcutaneously after sensitivity to serum developed. The patient recovered.

The general treatment and nursing of patients with meningitis are most important. They should be disturbed as little as possible, and if they are restless, sedatives must be administered. Adequate nourishment should be given and the fluid intake must be sufficient. Care should be taken to prevent acidosis. Retention sometimes occurs, so

that catheterization is necessary. Constipation is the rule and enemas or high colonic irrigations are better than purgatives.

Our mortality has varied considerably in different years. From July 1, 1917, to July 1, 1918, 112 patients were treated with a mortality of 19 per cent. From July 1, 1918, to July 1, 1919, 78 patients received treatment with a mortality of 20.5 per cent. Our average mortality has been higher than this. The last 100 cases that were treated under our supervision showed a mortality of 23 per cent. Of the 23 patients who died, 4 had only 1 or 2 injections of serum. One of these had pneumonia also; 5 others had pneumonia either immediately at the onset or during the course of the disease; 1 showed congestion of the lung which was apparently developing into a pneumonia; 1 had a complicating endocarditis; and 1 a brain abscess.

Meningitis is certainly a very serious disease and every effort should be made to produce a more effective serum. We have done some experimental work in producing an antibody. The results are encouraging but the preparation of the antibody is still in an experimental stage.

The sequelae of meningitis are serious but fortunately relatively uncommon. The most important and frequent sequela is deafness. In following up our recovered cases some years ago, we found that nearly 8 per cent had an impairment of hearing or were totally deaf; 2.1 per cent had defects of vision. This usually takes the form of panophthalmitis and is usually limited to one eye. Mental deterioration is most unusual unless there is a hydrocephalus. Paralyzes may occur in the course of the disease, but except for strabismus, they usually disappear. A transverse myelitis is very rare.

The response of many patients to serum treatment is almost spectacular and the results are highly gratifying.

Medicine and the State

Practical Problems in the Serum Therapy of Meningococcus Meningitis^{*}

AUGUSTUS WADSWORTH, M. D., F. A. P. H. A.

Division of Laboratories and Research, New York State Department of Health, Albany, N. Y.

THE specific therapy of any infectious disease depends upon its pathology in the broadest sense—the character and virulence of the incitant, its distribution in the tissues, and the nature and extent of the pathological processes in the various tissues and organs of the body. Fundamentally, it depends upon the subtle cellular susceptibilities of the invading parasite on the one hand, and of the tissues of the host on the other; hence the importance of information concerning the meningococcus and its various activities in relation to the human subject as a susceptible or relatively insusceptible host. Such information is, unfortunately, quite fragmentary but none the less significant.

Our knowledge of the virulence and pathogenicity of the meningococcus in the experimental study of animal infection is meager because it has been difficult until recently to differentiate between the toxic effects of cultures inoculated into animals and the changes induced as a result of infection, with the development of the organism in the tissues. The widely varying severity of the disease as illustrated by the mild and the fulminating, toxic forms indicates widely varying degrees of susceptibility in the human subject. The fact that in epidemics only a comparatively small proportion of the population is involved, and that the cases are often scattered, suggests general, though relative, insusceptibility. The distribution of the disease processes, largely limited to the meninges, and the comparatively infrequent occurrence of true metastatic involvement of other tissues, despite the bacteremia,† indicate, on the whole, a rather limited susceptibility of the human subject. Nevertheless, the epidemics of fulminating cases must be due largely to the presence of highly susceptible individuals in a crowded community, which is not usual.

^{*} Read before a Special Session of the Laboratory, Epidemiology, and Health Officers Sections of the American Public Health Association at the Fifty-ninth Annual Meeting at Fort Worth, Tex., October 27, 1930.

[†] Complications or sequelae, however, are not so uncommon.

Were it not for these facts, the severe outbreaks in epidemic form would more reasonably be attributed to the introduction and spread of a particularly virulent strain of meningococcus. Moreover, our studies, as well as those of other laboratories, have failed to identify any one strain that has been associated with the outbreaks on the Pacific Coast, in Chicago, Indianapolis, Detroit, or elsewhere in this country. Finally, the disease is now so generally endemic the world over that conditions of host susceptibility and crowding, especially in large industrial centers and in military camps, must be considered the determining factors in the absence of further data concerning the bacterial incitant.

Since the early work of Weichselbaum, the meningococcus has been detected in the pharynges of patients and also of healthy persons. From this focus infection spreads, involving the meninges, as pointed out by Weichselbaum and others, and also the blood stream as a bacteremia. Since the important studies of Herrick, the bacteremias have been considered especially significant. The dissemination of the organisms from person to person by the secretions of the upper respiratory tract must be quite readily accomplished and it has been found that the number of carriers is in direct proportion to the number of cases. Furthermore, it is evident that each case arises from contact with either a case or a carrier; hence the importance in severe epidemics of the investigation of carriers. Although the practical value of such work is not apparent, the various studies of the carrier state have indicated quite definitely the effect of crowding on the dissemination of the organism. The relative insusceptibility of the human subject and the fact that the carrier state is not usually so persistent as it is in other infectious diseases, such as diphtheria and pneumonia, doubtless account for the practical results obtained by simple measures to prevent crowding as compared with the complex search for, and isolation of, every carrier, a procedure which has not been proved necessary in outbreaks that occur in the civil population.

There has been a definite increase in the number of cases of meningitis in New York State since 1926, which, in view of the outbreaks in different sections of the country, has caused some concern. The Commissioner, Doctor Parran, at the suggestion of the Public Health Council, called a conference in May, 1930, in order to obtain complete information concerning the situation in various parts of the country. From the discussions and from our studies of the meningococcus strains, it is evident that, although no one strain has been recognized as responsible for any of these epidemics, from the standpoint of effective serum therapy, the relationship of the potency and valency of the

specific serum to the strain giving rise to the disease is of fundamental importance.

Strains of meningococci vary greatly in their serological and immunological reactions, the recently isolated strains often agglutinating only slightly or not at all; hence tests of the potency of the polyvalent serums with these non-agglutinable strains are often misleading—that is, fail to indicate whether or not the potency and valency of the serums are sufficiently high and broad to include these particular strains. In general, failure to agglutinate is an indication of lack of potency and valency in the serum but if the strain is in a non-agglutinable state the results may not be significant. In some instances, strains which were not agglutinated when first isolated were agglutinated later in the polyvalent serum. Not only do different strains agglutinate in widely varying degree but their antigenic action varies also when tested in the immunization of animals. The determination and study of the various strains of the meningococci are of the utmost importance in the investigation and control of epidemics and the serum therapy of the disease. Strains which are most representative of the different groups in their agglutinability and antigenic action are the strains which should be used for the production of antime-ningococcus serum that is intended for the treatment of the disease. The determination of the strains giving rise to outbreaks of the disease is important in order to be sure that the therapeutic serums possess adequate potency and valency.

The specific serum therapy of the disease is based upon the early work of Jochmann and of Flexner,^{1,2} who introduced the intraspinal injection of the serum, which proved in the extended studies of Flexner to be the effective method of specific treatment. The intraspinal method has been supplemented recently by intravenous injection of large quantities of this serum as a result chiefly of the work of Herrick, which demonstrated the importance of bacteremia, particularly in the early stages of the disease. Although undoubtedly a most valuable aid at times, treatment of the bacteremia by intravenous administration should not be so overstressed that it detracts from the more important introduction of the serum into the meninges, the real seat of the disease.

The importance of obtaining a broadly valent serum was recognized early by Flexner, Amoss, and others. Not only were representative strains of all groups of meningococci selected for the immunization of horses, but whenever a case failed to respond to serum treatment and the organism isolated from the spinal fluid failed to agglutinate in the serum, it was added to the series of cultures used in

the immunization. Thus, a broadly valent serum was assured and the reports of treatment were so favorable that it was generally adopted, not only in this country but also abroad. Unfortunately the antimeningococcus serums generally available for the treatment of cases lacked the potency and valency of the serums which Flexner used and the results of treatment with them have not been so encouraging. In many quarters the use of the serum has been practically abandoned, especially wherever there has been no improvement in potency and valency. During or toward the close of the World War, Amoss published a series of comparative tests of the different serums sold in the United States. Independently we made a series of similar tests with similar results. Our serum proved practically identical with Flexner's since the same strains and methods were used in its production, and the Flexner serum was used as a standard for the comparative testing of potency and valency. The results of these investigations were transmitted to the federal authorities and led to federal and state regulation of antimeningococcus serum, the distribution of standard cultures, and a control serum for comparative test of potency and valency. The federal standards have been advanced steadily since that time. Abroad there has been little or no effective standardization of these serums. Judging from information I was able to glean from a few personal conferences in Europe this summer, both in England and on the Continent, the results of serum therapy in meningitis have not been encouraging, to say the least.

When the laboratory first undertook the preparation and distribution of antimeningococcus serum for New York State the strains and methods of Flexner were adopted but, since many recently isolated strains failed to agglutinate and lacked antigenic activity, a thorough investigation of all the strains was made to determine which were most effective antigens and how many of them should be used in the immunization of horses to obtain serum of the highest potency and broadest valency. As a result of these investigations,^{*} published 10 years ago, it was found that both potency and valency might be increased by the proper selection of the strains and a reduction in the number to 4 or 6 of those which had proved to be the most effective antigens in the immunization of horses.

In view of the fragmentary knowledge of the virulence and pathogenicity of the various meningococci and the inadequacy of the available methods of standardization of serums in the laboratory as an indication of therapeutic potency in the treatment of cases, the change in method based upon these investigations seemed a very radical step. Accordingly, the serum was distributed to important medical centers

in order to obtain the most accurate and discriminating clinical opinion as to the therapeutic results. The reports were most encouraging and satisfactory in every particular, and it was evident that a real advance in the preparation of this serum had been made.' The reports for the past 10 years have uniformly confirmed this conclusion. Statistical comparisons of the results of the serum treatment of meningitis which have been reported in the literature have not been very satisfactory. The mortality varies greatly in different localities and in different series of cases, as well as the conditions under which they have been treated. Then, too, there has been no satisfactory standardization of the serums so that definite information concerning the tests of potency and valency of the serums used is not available.

Perhaps the most striking instance of the comparative potency of the 6-strain serum which we are now distributing is to be found in the report on a series of cases treated at the Post-Graduate Hospital in New York City by Wright, DeSanctis, and Sheplar.⁵ These came from one district in New York City and were evidently severe. The first 10 were treated with different commercial and other serums. All died. The remaining 34 received this 6-strain serum, with only 4 deaths: 2 were moribund when treated and 2 developed pneumonia. It is important to note that subsequent experience indicated that conditions relating to the character and severity of the cases had not changed, nor had the relative effectiveness of the serums which were substituted at intervals when the distribution of the 6-strain serum to the hospital was withheld. However, a much larger number of cases treated under as uniform conditions as possible is required to obtain significant comparative results.

The potency and valency of the serum used in the Flexner series and that used in ours were accurately determined by the accepted laboratory test of agglutination and in comparison with control serums, which indicated that the 6-strain serum as compared with the 20- or 60-strain serums previously used^{3,4} had a definitely higher potency and broader valency for practically all groups of the meningococci which it was practicable to study. Hence I consider most significant the comparison of 606 cases treated with this serum between 1920 and 1930, and the 1,300 reported by Flexner in 1913.⁶ In our series to date the mortality is 17.8 per cent; in Flexner's, 30.9 per cent, as compared with his estimated mortality in untreated cases of about 70 per cent. Among our 606 cases, however, there are 20 which I think should be eliminated—14 received their first dose of serum 48 hours antemortem—making the revised fatality rate 15 per cent in 586 cases.

The clinical reports, the statistical comparisons of the mortalities

in large series of cases, and the results of comparative testing in the laboratory all indicate the advance that has been made in the preparation of antimeningococcus serum.

To summarize the conclusions which are of practical interest to the health officer: Meningococcus meningitis develops as a result of contact with a case or a carrier, but only in susceptible persons. Crowding, coupled with the stress of industrial centers, or of military campaigns, is the most important condition favoring the spread of the disease in epidemic form, which is quite generally endemic the world over. In the outbreaks in this country during the past 3 years no particularly characteristic strain has been recognized as the incitant. The different strains vary widely in their virulence or toxicity, their agglutinability—especially when recently isolated—and their antigenic action as immunizing agents. In December, 1917, New York State established, and has since maintained independently, minimum standards of potency definitely in advance of those of the federal government. It is essential that the serums for specific treatment be prepared by immunization with a limited number of strains which are the most representative and most active antigenically. The minimum standards should assure the highest degrees of potency and valency. The agglutination of such serums against recently isolated strains is not a reliable criterion of therapeutic potency. Standardization by the agglutination reaction with standard strains and control serum, however, is generally quite reliable.

The serum is given intraspinaly, the dosage depending upon the amount of fluid withdrawn. It should be given slowly and at intervals of approximately 12 hours until there is definite evidence of improvement. Intravenous administration of even larger doses during the earliest stages may be helpful but should only supplement and not supplant the intraspinal treatment.

Control Measures Adopted for Epidemic Cerebrospinal Fever on Ships*

J. C. GEIGER, M. D., F. A. P. H. A.

George Williams Hooper Foundation for Medical Research, University of California Medical School, San Francisco, Calif.

EPIDEMIC cerebrospinal fever occurs with piquant irregularity. Indeed, since the outbreak of 1904–1905, this disease has been sometimes epidemic, sometimes sporadic without complete cessation. Europe, Africa, South America, Australia, and China have been harassed. In other words, the disease has been pandemic practically over the world between 1904 and 1910 with never a really quiescent period in the United States or Europe. In fact, in the United States, each winter, in one locality as another, groups of cases have occurred. There is no doubt that severe epidemics leave viable focuses which add to the continuity of the propagation of the disease. The meningococcus only survives in nature in the human being. The epidemiology is by no means as simple as it seems. The epidemiology of pneumonia has often been contrasted with that of epidemic cerebrospinal fever. Apparently, the latter only reaches epidemic proportions not so much through case contact as from chronic carriers. Constituting as they do often unsuspected and innocent participants, they become malevolent agencies in the spread of the disease usually in the vicinity of cases. The carriers generally outnumber the cases many to one; consequently their detection and control—mainly because of the fact that the meningococcus is decidedly selective in medium, infinitely sensitive to environment and technically difficult to recognize culturally—make boggy-haunted creatures of the painstaking and careful health officials. The sporadic character of many of the cases indicates a widespread resistance to the disease in the general population. This assumed resistance may be to the causative germ itself. The low case incidence is, however, laid at the door of the carrier, for it is stated, and often accepted, that the case incidence is dependent on the carrier incidence, reaching a comparatively high ratio, around 20. That this does not always hold true can be shown by the carrier incidence found aboard ships on which cerebrospinal fever had oc-

* Read before a Special Session of the Laboratory, Epidemiology, and Health Officers Sections of the American Public Health Association at the Fifty-ninth Annual Meeting at Fort Worth, Tex., October 27, 1930.

curred in 1928 and 1929. This was exceedingly low (2.5 to 4 per cent) even in the face of the known close contact so apparent in the type of steerage. Therefore, in some outbreaks, there may be an increased susceptibility, racial or other, to the particular causative type strains, and this was probably true in the Filipino cases that occurred on ships and elsewhere. Certainly, when large numbers of people are brought together from scattered communities, the presence of a carrier may be a foregone conclusion. Of practical importance are the measures to control and culture carriers. The results have not been brilliantly conclusive even under controlled conditions as in military camps. The carrier state is conceivably one important condition for consideration. It may persist for weeks but obtaining accurate results by the accepted present-day laboratory technic is decidedly uncertain. Therefore, control measures cannot be based alone on carrier detection. In fact, the health official must assume an expectant attitude in regard to all alleged control measures.

The history of cerebrospinal fever shows periods of high incidence recurring at fairly long intervals. The Great War years, 1915-1918, could be considered an epidemic period, also 1928-1929. The future is problematical. In the period 1913-1916, the case incidence could be considered low, or our normal expectancy 2 cases per 100,000 population. In 1918, it was 6 times greater than the assumed expectancy. The present increased incidence began about 1925. The City of New York showed, in 1928, a higher mortality rate than in the previous 18 years. The City of Chicago reported similar increased incidence.

*Public Health Reports*¹ stated in summarizing the situation that "the reported incidence of meningococcus meningitis for January, 1929, represented the highest attack rate for that disease since 1918." No mention was made of the Pacific Coast states. California, as well as Oregon and Washington, reported a decided rise in number of cases in 1926. In fact, this increase was manifest in Oregon in 1925. The important thing to observe is that the increased incidence was maintained for 1927 and 1928 for reported cases, and deaths reached the maximum in 1929 and declined in 1930. Likewise, cases were continuously being reported throughout the summer months for these periods. For instance, Washington reported in 1925, 55 cases and 39 deaths; in 1926, 190 cases and 84 deaths; in 1927, 162 cases and 95 deaths; in 1928, 123 cases and 95 deaths; in 1929, 304 cases and 116 deaths; and for January to August, 1930, 136 cases and 46 deaths. Oregon reported in 1925, 86 cases and 37 deaths; in 1926, 99 cases and 65 deaths; in 1927, 89 cases and 35 deaths; in 1928, 76 cases and 36 deaths; in 1929, 64 cases and 42 deaths; and for January to Au-

gust, 1930, 17 cases and 11 deaths. Oregon's definitely high mortality rate may be explained by incomplete reporting. California reported in 1925, 97 cases and 30 deaths; in 1926, 192 cases and 91 deaths; in 1927, 222 cases and 91 deaths; in 1928, 224 cases and 93 deaths; in 1929, 737 cases and 381 deaths; and for January to August, 1930, 268 cases and 120 deaths.

The situation as to cases in steerage passengers appeared at first to be not serious, and gave little concern to health and shipping officials. The disease was practically limited to steerage passengers of one line and mainly prevalent in one nationality, the Filipino, whose individual resistance to the causative strain of organism was probably low. The two Pacific Coast ports most affected were Seattle and San Francisco. Between November, 1928, and May, 1929, there occurred among the steerage passengers on 16 ships of one transportation company en route to these ports from the Orient, 193 cases of acute cerebrospinal fever; 166 of these were Filipinos; 21 Chinese; 2 Japanese, and 4—2 of which were Chinese—members of the crew. Many of these died at sea. It was interesting to note that cases were found on 5 ships on 2 different trips. These trips approximate 60 days in length. On 3 ships there occurred a small number of cases on the first trip. On the next trip from the Orient, they were remarkably increased, reaching 43. There were no cases reported on any of the trips to the Orient from the States. Search of the crew of 2 ships for carriers on two occasions revealed a few who were promptly removed before sailing. Both ships had, however, further cases of meningitis in Filipino steerage passengers on their return from the Orient. Until such measures as laboratory search for carriers and reasonable control of contacts were fully established in the ports affected, contact cases in the general population appeared, probably as a result. Such contact cases should primarily be most prominent in resident Filipinos.

Oregon, however, reported for 1929 only 1 case and 1 death in Filipinos and that in April; Washington reported 26 cases or approximately 10 per cent of the total, and 3 deaths in Filipinos exclusive of ship cases; and in California—where data are available as to Filipino nationality only in the City and County of San Francisco, the County of San Joaquin, the County of Monterey, and the City of Sacramento—San Francisco reported, January to June, 1929, 15 cases in Filipinos exclusive of ship cases; Monterey County 33 cases; San Joaquin County 14 cases and 6 deaths; and the City of Sacramento 3 cases since the beginning of 1929. The available data would indicate that there were 65, or approximately 10 per cent of the total, possible contact cases in Filipinos in California for the above communities and

municable diseases and the technic of isolation. The ships in question have what is known as "hatch" type of steerages. Contact is, therefore, very intimate unless properly controlled, and racial characteristics of the Filipino insure that such contact under ordinary conditions is inevitable.

The following recommendations were promptly put into effect and have since been made a procedure of operation for control of any outbreak of communicable disease en route. Regulation No. 13, as to the establishment of an isolation area, proved to be of practical importance, but somewhat financially burdensome, because of loss of passenger space.

1. Careful medical inspection, including taking of temperatures, to be made at port of embarkation of all steerage passengers, and those who are sick with meningitis or undiagnosed febrile conditions, or who have presumably been in contact with cases of meningitis, should be refused embarkation. In epidemic periods, such passengers should be detained under medical supervision for 2 weeks, and if thought desirable, nasopharyngeal cultures taken for the presence of meningococci carriers.

2. En route, ships' surgeons should make a careful inspection of all steerage passengers twice daily, using the clinical thermometer to detect all cases of fever.

3. All those persons showing rise of temperature to be isolated until such time as a definite diagnosis can be made.

4. All cases of meningitis or those suspected of having meningitis should be immediately isolated and continued in isolation until arrival at suitable port of debarkation.

5. The nurse or attendant assigned to cases of meningitis should not care for persons suffering from any other disease.

6. Mess gear used by such patients should be immersed in a disinfecting solution or preferably boiled before being removed from the sick bay. Articles such as gauze, paper napkins, etc., used by the sick should be burned or thrown overboard, if at sea.

7. All general mess gear used by steerage passengers should be sterilized after each meal by immersion in actually boiling water for not less than 5 minutes.

8. Steerage compartments should be kept clean and amply ventilated. The type of ventilation and the amount of air change needed should be properly determined.

9. The captain of the ship should detail one of his officers to supervise, along with the ship's surgeon, the enforcement of the above recommendations and those that follow. The captain should hold these two officers absolutely responsible for the carrying out of these instructions.

10. So long as the situation with regard to cerebrospinal fever is acute, an additional practical or, preferably, a trained nurse should be detailed to each ship from infected ports as a special assistant to the ship's surgeon. Likewise, there should be picked out either from the steerage passengers or from the employees one man from each race to act as assistant to the chief surgeon.

11. That the hospital on the top aft deck should be set aside for the members of the crew with this proviso: that should a case of cerebrospinal fever be present it will not be quartered here as contact with the deck is entirely too prominent.

12. The hospital on the steerage deck should be retained as an isolation hospital for actual cases of cerebrospinal fever.

13. That a section of the steerage passenger quarters be set aside with its unit of wash rooms and toilets to be used as an isolation hospital for those becoming ill with symptoms not recognizable for the moment as those of cerebrospinal fever.

14. Special attendants should be arranged for those in the suspect hospital and those in the hospital proper. The food supply for these must be cooked separately and the dishes handled separately, washed thoroughly, and later boiled. These attendants must not come in contact with the other passengers. In the hospital proper and in the isolation unit there should be facilities for the cleansing and disinfecting of hands and the changing of gowns and masks before leaving cases of cerebrospinal fever. Therefore, it is necessary that the attendants, the doctors and the nurses wear suitable gowns and masks.

15. Individual glasses or paper cups should be supplied to the steerage passengers.

16. Steerage passengers should be made to sleep in opposite directions, that is, feet to head rather than head to head. In epidemic periods, unit isolation may be maintained by the use of canvas stretched between berths.

17. Sputum and vomitus cups should be supplied for each berth.

18. Ventilation should be sufficient but frequent changes must be maintained by the opening of port holes or by the non-closing of the forced draft.

19. Hot water, soap and towels, paper preferred, should be supplied to the steerage passengers every morning and at each meal time.

20. Food should be served on the plate and the passengers not allowed to dip into the general food supply. All dishes should be washed with soap and hot water and rinsed in boiling water. In times of the presence of cerebrospinal fever on board, it might be necessary to set up special hours for meals for each cook and establish specific areas for meals. Under no circumstances at the time of cases of cerebrospinal fever on board should there be allowed intermingling or any social contact as gambling, etc.

21. There should be frequent flushing of the steerage decks with soap and water. It is permissible, of course, to use a disinfectant like lysol, but the former is indicated.

22. No allowance of off-shore leave in infected ports for steerage passengers from the Philippines or members of the steerage crew. No admittance of native peddlers aboard ship.

23. There should be a supply of anti-meningitis serum, lumbar puncture needles, gowns and masks on board for the ship's surgeon and for nurses and attendants. In this connection, each ship's surgeon should receive specific instructions from the chief surgeon as to prophylaxis and control of communicable diseases. The officials of the steamship line should consider keeping their chief surgeon in touch with the ship by radio each day concerning any illness on board. Again, no physician should be employed in the future unless passed upon by the chief surgeon and after having received instructions as to the control and isolation of communicable diseases that may be encountered en route.

24. Under the existing circumstances, the presence of a case or a suspected case of cerebrospinal fever on board any ship should mean an increased and extraordinary activity to prevent its spread. To develop this end the commanding officer should lend his energy and every effort.

25. Should a case of communicable disease like cerebrospinal fever develop en route between ports like Hongkong and Honolulu arrangements should be made with the local health officer and port authorities in Honolulu that such case may be removed, thereby lessening contacts.

26. Once a case of meningitis develops en route in steerage space areas, the passengers in this area should be considered contacts and control measures instituted for the group.

27. Steerage passengers of like nationality should be placed together and, if practical, those from each port of call.

28. Steerage passengers from infected ports should not be accepted unless specific instructions to do so are issued or only when the known precautionary measures are in effect.

29. Disease conditions in ports visited should be ascertained by the ship's surgeon and the information conveyed to the chief surgeon.

Death of Dr. Charles Krumwiede

BY the death of Dr. Charles Krumwiede, Fellow A. P. H. A., for many years assistant director of the Health Department laboratories of New York City, the world of science loses an outstanding bacteriologist whose worth was recognized by scientists of every country. He had in charge the supervision of anti-toxins, serums and biological products for the use of the department or generally by practicing physicians, and he made his office an opportunity for widening medical knowledge.

Dr. Krumwiede in connection with Dr. William H. Park carried on in 1910 the experiments with bovine tuberculosis germs which confirmed the proof that they could infect human beings and thus led to the pasteurization of milk in the city and elsewhere in many countries. He devised improved methods for the isolation of the typhoid bacillus. His most recent discovery of importance was that the supposed bacillus of psittacosis, or parrot fever, was not guilty, the real culprit being an invisible filterable virus.

Dr. Krumwiede was at times an instructor in bacteriology in Bellevue and at New York University. He was an honored member of many scientific bodies. He was unknown to the general public, a fine example of the type of modest, quiet, self-effacing scientists in government employ who for little pay and with scant applause do work of immense value to their community and their time.—*The World*, New York, N. Y., Dec. 31, 1930.

Incidence and Source of Epidemic Meningitis on the Pacific Coast 1929*

SENIOR SURGEON J. C. PERRY, F. A. P. H. A.

U. S. Public Health Service, San Francisco, Calif.

THE year 1929 was a fruitful one for epidemic meningitis, not only in certain western states but also in other parts of the United States, as well as in certain areas of the Orient.

It is not the purpose of this paper to deal with the epidemiology of the disease, but it is pertinent to point out that meningitis showed a higher rate than in any of the preceding 7 years. It was twice that of 1928, and more than 3 times that of any other year since 1925. This disease tends to occur in cycles and the large number of cases in 1929 was due to the gradual building up over a period of 5 years, as each succeeding year had shown a higher incidence than the preceding one. The crest of the epidemic wave was reached in the Pacific Coast states in 1929, but the disease continued prevalent in some adjacent states of the Rocky Mountain area until the spring of 1930 when subsidence was noted.

In addition to discussing the incidence in Pacific Coast and adjoining states, brief mention will be made of the occurrence of meningitis in the Orient and on ships having regular commercial relations between those ports and Pacific Coast ports in the United States. The latter is worthy of consideration as a possible factor in contributing to an increase in the number of cases, particularly in California and Washington.

MENINGITIS IN PACIFIC COAST STATES

There was a serious outbreak of epidemic meningitis in two Pacific Coast and two adjoining states. It is thought that during 1929 there were more cases and deaths from this disease in California than in any preceding year for a long period. There were 260 cases with 101 deaths in 1927, and 259 cases with 115 deaths in 1928. Both of these years showed an increase over preceding ones. The year 1929 showed

* Read before the Western Branch of the American Public Health Association at the First Annual Meeting in Salt Lake City, Utah, June 13, 1930.

the marked rise to 695 cases with 381 deaths. The majority of these occurred in the first half of the year, and from January 1 to August 31 there were 302 deaths distributed according to nationality as follows: Filipinos, 57; Mexicans, 39; Chinese, 16; Japanese, 6; giving 118 Orientals out of the total. According to sex, 218 were males and 84 were females.

The disease has shown a decline in the first quarter of 1930. There were 318 cases from January 1 to April 26, in 1929, against 185 cases for the corresponding period in 1930. Although it occurred in all parts of the state, there were definite sections where undue prevalence existed. The 5 principal ones were: Los Angeles County, 161 cases; San Francisco, 88 cases; Sacramento County, 71 cases; Monterey County, 63 cases; and San Joaquin County, 16 cases. In Los Angeles County the sufferers were whites and Mexicans; in Monterey County the majority were Filipinos employed in canneries or lettuce fields. Of 31 cases reported between January 1 and May 1, there were Filipinos, 19; Mexicans, 4; Japanese, 2; whites, 8. The first case was in a white person, one month before the first Filipino patient was reported. In Sacramento and San Joaquin Counties, a considerable number of the cases were Filipinos.

In San Francisco during the calendar year 1928, there were 37 cases: 35 whites and 2 Chinese. In 1929 there were 88 cases: 65 whites, 17 Filipinos and 6 Chinese. There were no cases among the Japanese. During the first quarter of 1929 there were 48 cases. For the same period in 1930 there were 15, all whites except one Filipino. It will be noted that the number of cases among the Filipinos in 1929 was large in proportion to their number.

The non-local cases developing and treated in San Francisco are not included, as they are not properly chargeable against that city.

The State of Washington showed an increase over 1928, the crest being reached in 1929. This state, like California, has active commercial relations with the Orient, and a number of vessels arrived at Seattle with meningitis among the Filipino steerage passengers. Exclusive of ship cases there were reported 221 cases and 70 deaths in 1929, the highest number for any recent year. The following nationalities were affected: whites, 178; Filipinos, 28; Japanese, 12; Chinese, 3. The cases resulting from infection on shipboard were 83, with 18 deaths: 78 Filipinos, 4 Chinese, and 1 Japanese.

Oregon did not show an increase in 1929 over preceding years; in fact the disease was less than in 1927 and 1928. In 1926 there were 99 cases; in 1927, 89; 1928, 76; and in 1929, 64. There has been a further diminution in cases in 1930. From January to April, 1929,

there were 31 cases; for the first 4 months in 1930, 11 cases. In 1929 all the cases were whites except 1 Filipino. There are few of the latter in Oregon outside of a settlement in Portland, which does not seem to have suffered from the disease to any degree.

INCIDENCE OF THE DISEASE IN ADJOINING STATES

For comparative purposes the incidence in states adjoining those of the Pacific Coast is of interest. In all of these the number of Filipinos is negligible, very few being domiciled therein. Two of these states had a severe outbreak of meningitis in 1929, a larger number of cases in proportion to population than in either California or Washington, where stress has been laid on the Filipino.

In Arizona there were 76 cases in 1928 and a marked rise in 1929 to 287. For the first quarter of 1929 there were 172 cases and for the same period in 1930, 115. While a diminution has occurred it is less than in other sections under consideration. In this state the records do not show the nationality of those affected, but the State Health Officer advises that there are not large numbers of Filipinos and there has not been any prevalence of meningitis among them.

Idaho had 99 cases of meningitis in 1928, and an increase in 1929 to 256. This incidence is high in comparison to population, and the outbreak must be considered severe. It is estimated that not over 10 per cent of the cases were foreigners. There are practically no Filipinos in the state and there was no meningitis among them.

Nevada had little meningitis in 1929, in fact probably not more than could be considered normal. During 1928 there were 17 cases and in 1929, 21. There are few Filipinos and no case of meningitis occurred in this nationality. The disease for the first quarter of 1930 shows no variation from that of the same period in 1929.

MENINGITIS AMONG STEERAGE PASSENGERS ON VESSELS FROM THE ORIENT

A review of the cases of meningitis occurring on vessels from Manila and Chinese ports in 1929 and the years immediately preceding is of interest in showing that the Orient was subject to the same cyclical increase that occurred in the United States. The incidence in the Orient cannot be computed, and the occurrence among passengers embarked at those ports must be considered in substantiation of the opinion advanced.

A study of the cases occurring at the Immigration Station at San Francisco, where Chinese and Japanese passengers are detained, indicates the prevalence of meningitis in Chinese areas, and there is evi-

dence that a severe outbreak occurred in Shanghai. It is believed, however, that Hong Kong was the source in this particular instance, as few steerage passengers are brought from Shanghai and none were embarked at that port during the height of the epidemic. No cases originated at the Immigration Station during the fiscal years 1925 to 1928 inclusive. With the increase of meningitis in the fall of 1928 a different story unfolds, as there were 9 cases at this station in 1929, all Chinese.

The incidence of meningitis among the steerage passengers on vessels arriving at San Francisco from the Orient is as follows: 1925, 0; 1926, 1; 1927, 2; 1928, 1; 1929, 14. A further consideration of vessels having had or having meningitis among their personnel in 1929 seems warranted in order to show any relation that might exist between that infection and the occurrence of cases on the Pacific Coast. The first ship in this category arrived on October 3, 1928, and from that date to May 29, 1929, there were 14 vessels with a total of 126 cases of meningitis. Space will not permit of an analysis of these cases, but as the vessel that arrived on March 20, 1929, furnishes an excellent example of the effects of overcrowding and failure to isolate cases promptly, further consideration of it is justifiable.

There were reported 21 cases of meningitis with 4 deaths en route, all Filipinos, except 1 white seaman. Upon arrival there were 13 cases in the ship's hospital and during inspection at quarantine 6 additional cases were found. There were 27 cases among 581 Filipinos from Manila, but none among 171 Chinese from Hong Kong. The first cases occurred on the 10th day from Manila, and the others as follows: March 3, 1; March 8, 1; March 9, 2; March 11, 1; March 14, 6; March 15, 2; March 17, 4; March 18, 2; March 19, 2; March 20, 6. The last were detected at quarantine inspection. This vessel was crowded with steerage passengers; there were 647 when leaving Manila; 708 when leaving Hong Kong, and 448 upon arrival at San Francisco. During 10 days' detention of passengers at the Quarantine Station 11 cases of meningitis developed and 2 among them after discharge, a total of 40. Advises state that 20 cases developed among the Filipinos landed and detained at Honolulu, making approximately 60 cases among the 647 Filipino steerage passengers brought by this vessel.

Two other vessels arrived with high incidence of infection; one had 27 cases: 22 Filipinos and 5 Chinese; the other, 25 cases with 12 deaths: 21 Filipinos and 4 Chinese. Twenty-two of these occurred in adjoining compartments.

After May 29, 1929, no other vessels arrived having had menin-

gitis until December of that year. Chargeable against 1930 there have been only 4 vessels with a total of 8 cases of meningitis: 3 arrivals at San Francisco and 1 at Seattle.

SUMMARY OF REPORTED CASES OF EPIDEMIC MENINGITIS AMONG STEERAGE PASSENGERS ON VESSELS ARRIVING AT SAN FRANCISCO FROM OCT. 3, 1928, TO MAY, 1929

<i>Race</i>	<i>Cases</i>	<i>Deaths</i>
Filipinos	99	19
Chinese	22	9
Japanese	1	0
White	4	2
Total	126	30

The number of deaths may not be accurate, and is probably nearer 50 per cent.

The 126 cases occurred on 14 vessels, and if we assume that each carried an average number of 600 steerage passengers, we have this large number of cases in an approximate population of 8,400. When comparison is made with San Francisco, the effects of crowding and contact infection are astounding. For example, there were 73 cases in San Francisco, in a population of 625,000, during the period that 126 cases occurred on vessels with an approximate population of 8,400.

DISCUSSION

The history of meningitis on some vessels indicated Manila was the source of infection, and in others Hong Kong. The infection was introduced by embarkation of carriers or mild cases, and secondary cases developed from contact. Under conditions existing in the steerage, which was crowded, with free communication between compartments, it is no surprise that meningitis spread. The steerage passengers were bunked in close apposition to each other and there was every opportunity for the exchange of nose and throat infections. Under these conditions, meningitis has proved a dangerous contagious disease.

Cultures from 3,287 contacts gave 85 carriers. Ninety per cent of the carriers became negative in 7 days, and all in 14 days except 1 who was positive for 6 weeks.

During detention in quarantine there developed 11 cases and 2 after 10 days' detention.

RELATION OF MENINGITIS ON VESSELS TO THE INCIDENCE OF THE DISEASE IN PACIFIC COAST STATES

I believe that the high incidence of meningitis in the Pacific Coast and adjoining states was independent of the prevalence of the disease in the Orient and the infection on arriving vessels. It was a cumula-

tive effect from preceding years, as occurs in the cyclical development of outbreaks of meningitis. In various parts of the United States and other countries 1929 was a meningitis year.

It has been shown that Filipinos played no part in serious outbreaks in 2 adjoining states. No case was reported among the Filipinos in San Francisco during 1928, and it was not until February, 1929, that cases of meningitis commenced to appear among them.

Although the arrivals of Filipinos and Chinese from infected ports and on ships with the disease on board cannot be held responsible for the outbreak of meningitis in Pacific Coast states, such arrivals in large numbers might have been a contributing factor in adding to the number of cases in specific areas where they concentrated. The Filipino appears susceptible to the disease and no doubt some carriers were landed before the quarantine regulations were enforced, and probably after. These people crowd together in boarding houses or small flats for economic reasons, and consequently favorable conditions are created for the development of the disease among them.

Fifty Years of Applied Bacteriology

APPROXIMATELY half a century ago medical science enjoyed an unparalleled advance as a result of the introduction of practical laboratory methods in the study of bacteria. There are still with us a few of the pioneers of that remarkable era, notably our dearly beloved Welch. But for the medical profession at large the epoch-making work of the late 70's and early 80's is fast becoming a matter of history.

Impressed by the importance of preserving what concrete relics of this interesting period can still be rescued from obscurity, the writer suggests the advisability of organizing an exhibit to commemorate "Fifty Years of Applied Bacteriology," collecting for this purpose whatever interesting historical material may be hidden away, dust covered and forgotten, in some of the older bacteriological laboratories. Apparatus long since discarded as obsolete, old microscopes, microtomes, glass plates and levelling stands, roll cultures, illustrations of alleged disease germs, old text books, original publications of historic interest, reproductions of early culture flasks, these and many other articles may still be available. Fifty years hence much of this valuable historical material will have been lost forever.

What group interested in the history of medicine will act on this suggestion before it is too late?—C. F. B., *Weekly Bull.*, New York, N. Y., Dec. 27, 1930.

White House Conference on Child Health and Protection

Preliminary Program of

Final Session

SECTION I—MEDICAL SERVICE

February 19, 20, 21, 1931

Washington, D. C.

Samuel Mc C. Hamill, M.D., Chairman

Committee A—Growth and Development, Kenneth D. Blackfan, M.D., Chairman, Professor of Pediatrics, Harvard University Medical School.

Committee B—Prenatal and Maternal Care, Fred Lyman Adair, M.D., Chairman, Professor of Obstetrics and Gynecology, University of Chicago.

Committee C—Medical Care for Children, Philip Van Ingen, M.D., Chairman, Clinical Professor, Diseases of Children, Columbia University College of Physicians and Surgeons.

Thursday, February 19, 1931

9:00 A.M. Opening Session for All Committees

Address of Welcome—Ray Lyman Wilbur, M.D., Chairman of the Conference

Committee A—Growth and Development

Thursday

9:30–11:00 A.M.

General Considerations—Edwin Bidwell Wilson, Ph.D., Professor of Vital Statistics, Harvard School of Public Health

Thursday

11:00 A.M.–1:00 P.M.

Anatomical Considerations—Richard E. Scammon, Ph.D., Professor of Anatomy, University of Chicago

Thursday

2:30–4:30 P.M.

Physiological Considerations—A. J. Carlson, M.D., Sc.D., Professor of Physiology, University of Chicago

Thursday

8:00 P.M. (See Program of Committee C—Medical Care for Children)

Friday, February 20, 1931

9:30 A.M. (See Program of Committee B—Prenatal and Maternal Care)
(See Program of Committee C—Medical Care for Children)

Friday

2:00–3:30 P.M.

Appraisal of the Child

1. Physical Status—T. Wingate Todd, M.B., F.R.C.S., Professor of Anatomy, Western Reserve University School of Medicine

Friday

3:30-5:00 P.M.

Appraisal of the Child

2. Mental Status—Douglas A. Thom, M.D., Director, Division for Mental Hygiene, Massachusetts Department of Mental Diseases

Friday

8:00 P.M.

Nutrition—Lafayette B. Mendel, Ph.D., Sc.D., Professor of Physiological Chemistry, Yale University

Committee B—Prenatal and Maternal Care

Thursday, February 19, 1931

9:30-11:30 A.M.

Prenatal, Maternal and Early Infant Care—John Osborn Polak, M.D., Professor of Obstetrics and Gynecology, Long Island College Hospital School of Medicine

Thursday

11:30 A.M.-12:30 P.M.

Interested Organizations—Robert D. Mussey, M.D., Professor of Obstetrics University of Minnesota (Mayo Foundation)

Thursday

2:00-5:30 P.M.

Factors and Causes of Fetal, Early Infant and Maternal Morbidity and Mortality—Hugo Ehrenfest, M.D., Assistant Professor of Obstetrics and Gynecology, Washington University Medical School

Thursday

8:00 P.M. (See Program of Committee C—Medical Care for Children)

Friday, February 20, 1931

9:00-10:15 A.M.

Obstetric Teaching and Education of Midwives—James Robert McCord, M.D., Professor of Obstetrics and Gynecology, Emory University

Friday

10:15-11:30 A.M.

Obstetric Teaching and Education of Nurses and Nursing Attendants—George W. Kosmak, M.D., Editor, American Journal of Obstetrics and Gynecology

Friday

11:30 A.M.-12:30 P.M.

Teaching and Education of the Laity and Social Workers—Robert L. De-Normandie, M.D., Instructor in Obstetrics, Harvard University Medical School

Friday

9:00 A.M.-12:30 P.M.

Basic Sciences and Their Relation to Maternal and Fetal Problems—Leslie B. Arey, Ph.D.

Friday

2:00-5:30 P.M.

Obstetric Teaching and Education of Physicians

1. Correlation of Instruction in the Basic Sciences with that in Obstetrics from:

- a. Viewpoint of Basic Sciences—Leslie B. Arey, Ph.D., Professor of Anatomy, Northwestern University Medical School
- b. Viewpoint of Obstetrics—J. M. H. Rowland, M.D., Professor of Obstetrics, University of Maryland School of Medicine
2. Undergraduate Education—Palmer Findley, M.D., President Central Association of Obstetrics and Gynecology
3. Graduate Education—Rudolph W. Holmes, M.D., Associate Professor of Obstetrics, Northwestern University Medical School
4. Education and other Obstetric Requirements for Granting Degree of Doctor of Medicine, Licensing to Practice, and for Specialization—Walter T. Dannreuther, M.D., Professor of Gynecology, New York Post-Graduate Medical School

Friday

8:00 P.M. (See Program of Committee A—Growth and Development)

Committee C—Medical Care for Children

Thursday, February 19, 1931

9:30 A.M.—1:00 P.M.

Convalescent Care—Adrian V. S. Lambert, M.D., Chairman, Executive Committee on Convalescence, Welfare Council of New York, N. Y.

Foster Homes for Convalescence—Ida M. Cannon, R.N., Chief of Social Service, Massachusetts General Hospital

Thursday

9:30 A.M.—1:00 P.M.

Psychiatry and Psychology—Bronson Crothers, M.D., Assistant Professor of Pediatrics, Harvard University Medical School, Neurologist to Children's Hospital, Boston, Mass.

Thursday

9:30 A.M.—1:00 P.M.

Orthopedics and Body Mechanics—Robert Bayley Osgood, M.D., Professor of Orthopedic Surgery, Harvard University Medical School

Thursday

9:30 A.M.—1:00 P.M.

Nursing—Stella Goostray, R.N., Secretary, National League of Nursing Education, Superintendent, School of Nursing, Children's Hospital, Boston

Thursday

2:30–5:00 P.M.

Hospitals and Dispensaries—Clifford G. Grulee, M.D., Clinical Professor of Pediatrics, Rush Medical College (Lantern Slides)

Thursday

8:00 P.M.

Preventive Measures—Philip Van Ingen, M.D., Chairman of the Committee
Report on a National Survey to Determine the Extent to which Preventive Medical and Dental Services Reach Preschool Children—George T. Palmer, Dr.P.H., Director of Research, American Child Health Association (Lantern Slides)

1. In 158 cities based upon approximately 85,000 families interviewed. Relative standing of states in proportion of preschool children having had health examinations, dental health examinations, vaccination against smallpox and diphtheria immunization. Influence of economic status and age.

2. In rural areas in 42 states based upon approximately 25,000 families interviewed. Relative standing of states in proportion of preschool children reached. Variations at different age levels. Geographic differences in hospital and home delivery service and attendance at birth. Accessibility of medical, dental and hospital service.

Conclusions and Recommendations—Samuel McC. Hamill, M.D., Chairman of the Section

Friday, February 20, 1931

9:30 A.M.—12:30 P.M.

Pediatric Education—Borden S. Veeder, M.D., Professor of Clinical Pediatrics, Washington University School of Medicine (Lantern Slides)

Friday

2:15–5:00 P.M.

Medical Social Service—Ida M. Cannon, R.N., Chief of Social Service, Massachusetts General Hospital

Friday

2:15–5:00 P.M.

Health Centers—J. H. Mason Knox, Jr., M.D., Chief, Bureau of Child Hygiene, State of Maryland Department of Health; and Mrs. Berthold Strauss, Vice-President, Community Health Center, Philadelphia, Pa.

Relation of the Nutritionist to the Health Program—Lucy H. Gillett, M.A., Superintendent, Nutrition Bureau Association for Improving the Condition of the Poor

Friday

2:15–5:00 P.M.

Dentistry and Oral Hygiene—Percy R. Howe, D.D.S., D.Sc.

Friday

8:00 P.M. (See Program of Committee A—Growth and Development)

Saturday, February 21, 1931

9:30 A.M. Joint Session for All Committees

Summaries of Findings and Recommendations of the Committees

1. Committee A—Growth and Development—Kenneth D. Blackfan, M.D., Chairman of the Committee
2. Committee B—Prenatal and Maternal Care—Fred Lyman Adair, M.D., Chairman of the Committee
3. Committee C—Medical Care for Children—Philip Van Ingen, M.D., Chairman of the Committee

The Discovery of *Trichina Spiralis*

THE recent outbreak of trichinosis in Stuttgart has kindled interest in a disease epidemics of which are uncommon in this country. The story of the discovery of the parasite¹ is obscured by priority claims which lack historical perspective. Even the new edition of Osler's *Principles and Practice*—a textbook famed for its historical atmosphere—gives a regrettably incomplete account of the history of trichinosis, with no mention of Paget's name.

The main events in the story may briefly be summarized. F. Tiedemann in 1822 was the first to describe "white stony concretions" in human muscle (analyzed by L. Gmelin), though he never suspected their parasitic origin. In 1833 John Hilton described minute cysticerci in which microscopically he was unable to detect any organization. On February 2, 1835, at St. Bartholomew's Hospital, James Paget was dissecting the muscles of a subject when his scalpel became quickly and repeatedly blunt. Other students had attributed their similar experience to the presence in the muscles of "spicula of bone," and Wormald, the senior demonstrator of anatomy, had seen at least 20 bodies studded with whitish specks. Paget, however, was the first to suspect their animal nature, which he confirmed with the aid of Robert Browne's simple microscope—for St. Bartholomew's did not even possess a dissecting lens. He made careful sketches of the worm, preserved in the library of the Royal College of Surgeons of England, and lectured on his discovery to the Abernethian Society of St. Bartholomew's Hospital, on February 6. On Stanley's suggestion he wrote an account of his work for the *London Medical Gazette*. This was never published, but the manuscript may be seen at the College of Surgeons.

A specimen of infected muscle was sent to Richard Owen, who established the nematoid nature of the worm, named it *Trichina spiralis*, and, taking the credit for its discovery, earned the applause of his professional brethren. Paget's behavior in this melancholy episode was admirable. His original specimen was deposited in St. Bartholomew's Hospital museum. Fifty years later it was thrown away, as time had reduced it to dust and ashes.

The life history of the trichina was fully worked out by Herbst, Virchow, Zenker, and Kuhne, who completed a discovery made by a medical student of twenty-one years.—*Brit. M. J.*, Oct. 11, 1930, p. 610.

This statement omits entirely any reference to the most significant discovery among those of the many investigators who contributed to working out the life history. It was the demonstration of a similar encysted stage in the pig. For this the distinguished American physician and investigator Dr. Joseph Leidy of Philadelphia was responsible. The older authors overlooked the leading part he played in laying the foundations of parasitology, perhaps by virtue of his outstanding contributions in other fields. This oversight was adequately corrected by numerous addresses delivered on the occasion of the Leidy centenary in Philadelphia during September, 1923.

Leidy's part in the elucidation of the life history of trichina was one of the most significant contributions to research, giving the key to unlock the story of the life cycle of this parasite and at the same time furnishing the foundation for a simple and effective method for the prevention of the disease.

In 1846 Leidy recorded the discovery of minute encysted worms in the hog. He wrote that he "could perceive no distinction between it and specimens of *Trichina spiralis* which he had met with in several human subjects."²

CONTROL OF MENINGOCOCCUS MENINGITIS

THE incidence of meningococcus meningitis has been rising steadily through the last five years¹ and has been accompanied by local epidemics of some severity and with high fatality rates. The number of carriers has also been higher than in former reports. Flack² found 2 per cent of the community and 8 per cent of the contacts to be carriers, whereas in a recent epidemic in Detroit 6 per cent of unexposed members of the community and 46 per cent of contacts were found to be carriers. Segregation of carriers is usually considered impracticable.³ When untreated the carrier stage has been found to persist on the average for 4½ weeks in contact carriers, and for 3½ weeks in carriers who are not known to have been contacts.⁴

Thirteen years ago Simon Flexner⁵ emphasized the importance of treating carriers as a potential source of future cases and recommended the method of Dunham and Dakin⁶—the use of an oil spray of dichloramine T. He stated that artificial immunization through inoculation of killed cultures “has failed completely.”

Since that time no constructive suggestions of serious importance have been offered, although the subject has been frequently discussed. The revival of the method of inoculation with apparent success is therefore worthy of some attention.

In the winter of 1927, Dr. Manoussakis found himself confronted with an epidemic in the cavalry barracks at Athens.⁷ Of 150 contacts 70 per cent were found to be carriers. He prepared a vaccine by cul-

ture from the puncture fluid of the original case. The vaccine was killed by heat at 56° C. for 30 minutes and administered in 2 doses of 2 and 3 milliards respectively at an interval of 7 days. The number of carriers among the contacts was quite promptly reduced to 2 per cent and the threatened epidemic was averted.

The same method was used during 2 threatened epidemics in the winter of 1929 and in one instance during the present year (1930). In discussing his apparent success on each of these occasions Dr. Manoussakis emphasizes: (1) that the vaccine was freshly prepared, and (2) that the strain employed was absolutely specific. In view of the known variety of strains and of the recent recognition of an organism hitherto undescribed, the latter point is evidently significant.

MR. CALVER RESIGNS AS EXECUTIVE SECRETARY

HOMER N. CALVER resigned on December 31 as Executive Secretary of the American Public Health Association, after seven and one-half years' service. This announcement will be received by all the friends of the Association with regret.

The Executive Board accepted Mr. Calver's resignation with reluctance upon his request for release from his obligations, and in so doing, spread the following resolution on its minutes in behalf of the Association:

RESOLVED, that during the term of his office, Homer N. Calver as Executive Secretary of the American Public Health Association has put the interests of the Association before all others, has been loyal to his responsibilities, energetic and resourceful in carrying out the intent and directions of the officers and members, patient and equable in the presence of conflicting opinion, and counsel, systematic and thorough in making effective the changes in plan and scope of the work and organization of the Association, twice radically altered during his term of office, scrupulously careful in all matters of income and expenditures of the Association, and at all times consistently upholding high professional standards for the public health profession in dealing with commercial and business interests in the conduct of his office.

Every member of the Association and every reader of its *Journal*, no matter how casual his observation of the affairs of the Association

may have been, cannot fail to be struck with the growth and development of the organization during Mr. Calver's competent administration. Some comparisons between situations in July, 1923, when Mr. Calver took office, and now, may be interesting.

When he took office, the Association had about 2,600 members. It now has 4,300 members, not including an additional 2,500 members in the affiliated state societies.

The number of these societies has grown from 3 to 15. The relationships of the societies to the parent organization have been clarified and strengthened.

To the Annual Meetings of the Association Mr. Calver has made a contribution that cannot be overestimated. He has devoted himself with great zeal to their organization and has developed a most efficient technic for their management and operation. Through his efforts and vision, excellent programs have been built up, the range of subject matter has become infinitely wider, and the standards of papers notice-

HOMER N. CALVER

ably raised. The Annual Meetings have become distinguished alike for scientific pronouncements and attendance. This definite rise in quality attracts increasingly large audiences of Fellows and members. The attendance at the Boston meeting in 1923 was 904. The following years show steady gains, reaching the high-water mark of 2,577 in Chicago in 1928. In 1929 and 1930 registrations were about 1,400 and it is safe to prophesy that this figure, representing a gain in attendance of 500 or more, will be reached for several years to come. At Mr. Calver's urging, the Association has determined to finance Annual Meetings from the sale of exhibit space instead of taxing the hostess city, as in the past. Income from exhibits has increased from \$1,950 in 1922 to \$22,000 in 1928 and to \$17,500 in 1929.

The place of the sanitarian in public health has been memorialized through the establishment of the Sedgwick Memorial Medal, which has been to a considerable extent brought about through the efforts of Mr. Calver.

The American Journal of Public Health, of which Mr. Calver was

editor for five years, and the supervision of which has been his responsibility throughout, has increased its circulation from some 3,700 copies per month to over 6,500 copies. Recently the purchase of *Nation's Health* was negotiated and it was combined with the *Journal* so that the publication now stands alone in this field.

The excess of all assets of the Association over liabilities at the time when Mr. Calver assumed direction of the Association was about \$3,500. With careful husbanding this has grown to a net wealth of nearly \$28,000. For the fiscal year 1923, the income from all sources except grants for special purposes was in the neighborhood of \$40,000. This year the comparable income is \$123,000. These figures are significant because this income, which must be earned largely through self-supporting activities, has increased without a corresponding increase in the dues of members. Although these figures may seem small in these days of million dollar enterprises, their importance in terms of progress of the Association are most significant. Of even greater value are the many constructive changes in administration which have been brought about, giving stability of organization and clarity of function to the increasingly numerous elements of the Association.

These activities, which are casually accepted and taken for granted by the members of the American Public Health Association, have attracted the attention of those who view general public health development, and as an indication of their significance in the field of public health promotion, the Ling Medal for distinguished service in behalf of health and child welfare was presented to Mr. Calver as Executive Secretary of the Association at the Fifty-ninth Annual Meeting in Fort Worth.

In seven and one-half years Mr. Calver has inscribed a record on the scrolls of the Association that will challenge his successor.

It is the sincere belief of those who have worked with Mr. Calver, and in doing so have had the opportunity to know his talents and his fitnesses, that he goes on to bigger and better things. He takes with him the good will and firm friendship of the members of the Association to which he has made such a splendid contribution.

BARBER SHOPS AND BARBERING

ALMOST everyone, male and female alike, now patronizes barbers. Even those women who frequent the beauty parlors go to barbers to have their hair trimmed.

In view of this, a report recently made by the Commissioner of

Public Health of Massachusetts' will be of interest to our readers. The Legislature of Massachusetts ordered an investigation of barbers and barbering, which was done partly through a questionnaire, to which 1,675 doctors responded. Only 16.3 per cent of the physicians had ever seen cases of diseases attributable to barber shops, but these reported 654 cases, 58 per cent of which were pustular skin infections, 35 per cent not classified, and 7 per cent described as nits, ringworm and syphilis. Thirty-four per cent of these cases were reported by 5 physicians, and the Commissioner has rightly questioned the diagnosis, at least as far as syphilis goes.

The newspapers took an interest in the investigation, and at their request, two public hearings were held at which 40 persons in a population of more than $4\frac{1}{4}$ million reported their conviction that they had been infected in barber shops; but of these, only 20 could be located, in 3 of which the claim seemed reasonable.

Inspection showed that of 2,439 shops in different sized communities, 34.5 per cent were in good condition, 18.4 per cent bad, while 46.6 per cent were mediocre. In general, the sanitary and esthetic conditions were proportionate to the prices charged by the shop.

The conclusions reached were that while there was room for improvement in the sanitary conditions of shops generally, only a negligible amount of skin infection could be traced to them, and there seemed to be no evidence indicating that further legislation regarding licensing, regulating, or inspecting of barber shops was needed at this time in Massachusetts.

The result of these studies, which have been carefully carried out, will be comforting to all who patronize barbers, assuming that Massachusetts represents fairly the rest of the country. The small number of skin infections reported, especially those due to lice and ringworm, is somewhat surprising. Certainly barbers come in contact with the great proportion of the population. In shaving, the external layers of the skin are frequently broken. Brushes and combs are used on hundreds of heads, often with imperfect or no washing or sterilization in between. The same shaving brush is used on many faces, but the necessities of the case require at least washing, which is generally done in hot water. The average barber is fond of blowing away the clipped hair, which furnishes abundant opportunity for droplet infection, and no barber discontinues his job on account of ordinary colds and sore throats. Like all places frequented by numbers of people, they afford opportunity for the spread of infection.

ASSOCIATION NEWS

DR. WALKER ACTING EXECUTIVE SECRETARY OF THE A. P. H. A.

Due to the resignation of Homer N Calver, as of January 1, 1931, W. Frank Walker, Dr.P.H., Secretary of the Committee on Administrative Practice, will serve as Acting Executive Secretary of the Association.

NEW SECRETARY FOR THE COMMITTEE ON FELLOWSHIP AND MEMBERSHIP

Cornelia Lyne, who has been Secretary of the Committee for the past year, has resigned to take a position as head of the Membership Department of the National Child Labor Committee of New York City. Marie L. Rose, formerly of the American Child Health Association, will succeed her, beginning January 15.

LABORATORY SECTION

Beginning with this issue, John F. Norton, Ph.D., takes over the preparation of the Laboratory Notes Section of the Journal, succeeding C. C. Young, D.P.H., whose many duties have made it impossible for him to continue to contribute to this department.

ACKNOWLEDGMENT

The following members of the Association sent in paid applications for new members during the 4-weeks membership drive:

L. H. Allwardt
Austin F. Barr, M.D.
V. H. Bassett, M.D.
Philip K. Bates, Ph.D.
F. A. Brink, M.D.

DEATH OF DR. HASTINGS

CHARLES J. HASTINGS, M.D.,
Medical Officer of Health, Toronto,
Ont., died on January 17. He has been
a member of the American Public Health

Association since 1911, a Fellow since
1922, and was elected to Honorary Fel-
lowship in 1926. He was President of
the Association in 1918.

PUBLIC HEALTH ADMINISTRATION

HENRY F. VAUGHAN, D. P. H.

Administrative Record Forms—

The Committee on Administrative Practice has recently issued an Administrative Cumulative Monthly Record Form which is based upon the *Appraisal Form*, which aims to give each month a picture of the quantity of service rendered in each of the various activities into which the *Appraisal Form* has been divided. Thus, under communicable disease control there are entries for the number of field visits by professional personnel for each of the more important reportable diseases. The number of cases hospitalized, and the number of children or adults immunized against certain diseases may also be entered on the form. For tuberculosis, there is provision for a record of all new cases admitted to the clinic, the number of contacts examined, the number of visits made in behalf of cases by field nurses, and the number of cases hospitalized, together with several other items.

In the same manner, closely adhering to the outline of the *Appraisal Form*, provision is made for a brief statement of vital statistics, care of the child including the school health service, food and milk, sanitation, laboratory, and popular health instruction. There are also additional forms covering cancer and heart disease control. Provision is also made for a summary which affords a comparison over a period of 4 years. The tables permit of extension and may be fitted to local needs. These record cards have been designed to keep the health administrator intimately informed as to progress being made by his department during the course of the year, and the cumulative record is designed pri-

marily as an aid in the preparation of the annual appraisal of health activities.

In 1927 the Committee on Administrative Practice issued its first record forms. There were four sets submitted at that time including forms for communicable disease service, laboratory, school health service, and public health nursing. In 1928, with the coöperation of the National Tuberculosis Association, tuberculosis record forms were developed, and in 1929, with the aid of the American Social Hygiene Association, forms were developed for venereal disease clinic service. The latest contribution of the committee may be had by addressing the Association headquarters.

Health Service in Alameda County

—In the spring of 1930, a survey was conducted of Alameda County, Calif., by an officer of the U. S. Public Health Service, to determine the quantity and quality of health work being performed, special attention being given to those agents supported by public funds and devoting their effort to public health or the care of the ambulatory sick.

Alameda County, with a population of 440,200, is located on the eastern shore of San Francisco Bay, and 91.4 per cent of the population is classed as urban, the principal cities being Oakland, Berkeley, and Alameda. One dollar and six cents per capita is being spent for public health work. According to the *Appraisal Form*, Oakland receives a rating of 629 points, Berkeley 752, and Alameda 638 points.

It is recommended that there be created a county health department to be

under the direction of a trained medical health officer of demonstrated ability, on a full-time basis, and that the county health department have administrative control of all public health services, preventive clinics, and field activities in the area served by such county health department. It is further recommended that a beginning be made by an expenditure of \$1.00 per capita for the included areas.—Joseph W. Mountin, Health and Hospital Services in Alameda County, Calif., Alameda County Tuberculosis Association, 1930.

Organized Health Service for Endicott Johnson Company—Beginning in 1916, with 1 full-time physician and 1 nurse, the Endicott Johnson Corporation of Binghamton, N. Y., has gradually extended its health and medical service until in 1928 nearly \$900,000 a year was being expended for the maintenance of three medical centers with hospital service, first aid stations, and various clinics. There are now over 100 employees including 28 physicians, 4 dentists, 5 dental hygienists, 67 trained nurses, and 4 bacteriologists. In the year 1928, \$161,000 was paid to full-time medical members of the staff, and \$39,000 to private practitioners engaged on a fee basis. The cost per individual, to whom the service was potentially available, was \$21.81 per annum, and the cost per individual in families which actually used the service was \$25.49 per annum. A survey made to compare the degree to which medical service was being used by the employees of the organization as compared with 100 families in the general population of the neighboring com-

munities shows that employees are not only visiting physicians more frequently, but earlier in the course of a given illness.—Niles Carpenter, Medical Care for Fifteen Thousand Workers and Their Families, *Publication No. 5*, Committee on Cost of Medical Care.

Milk-borne Outbreaks—Exclusive of New York City, it is estimated that about 80 per cent of the milk sold in the cities of New York State is pasteurized. From 1917 to 1929 inclusive, there have been 91 milk-borne outbreaks, an average of 7 yearly, with the total of 2,511 cases.

Typhoid fever has been responsible for 64, or 70 per cent, of the outbreaks, about 5 per cent of all reported cases of typhoid fever belonging to the milk-borne classification. At the same time, 16 per cent of all reported septic sore throat cases, 0.1 per cent of diphtheria, scarlet fever and poliomyelitis also were due to milk-borne outbreaks.

Of the 91 outbreaks, 89 were traced to raw milk, in 2 instances certified milk being involved. In only 2 instances is it alleged that pasteurized milk was involved, and in 1 instance involving 23 cases of typhoid fever, it is alleged that reinfection occurred after pasteurization. In the other instance involving 29 cases of scarlet fever, there is reason to believe that the milk was not actually pasteurized. Both outbreaks traced to certified milk occurred in one county. The first occurred in 1920 and included 70 cases of diphtheria, while the second occurred in 1924 and involved 60 cases of paratyphoid.—Paul B. Brooks, Milk-borne Outbreaks in New York State, *New York State J. Med.*, Dec. 1, 1930.

LABORATORY

JOHN F. NORTON, PH. D.

STUDIES OF CHEMICAL STERILIZATION AND BACTERIOSTASIS

I. A STANDARD INHIBITION CONTROL FOR GERMICIDAL TESTS

JUSTINA H. HILL.

*James Buchanan Brady Urological Institute, The Johns Hopkins Hospital,
Baltimore, Md.*

IN making bactericidal tests by any of the standard methods, or by modifications thereof, very careful inhibition controls must be made, in order to be sure that the apparent sterility of sub-cultures is not due to the presence of inhibitory amounts of the test drug, carried over in transfer. The omission of such controls from the earlier work is explicable on the basis that these tests were designed for the testing of phenols, most of which have a relatively low inhibitory action. When such tests, however, are used for the evaluation of many of the newer drugs, some of which have extremely high inhibitory action, the addition of accurate inhibition controls becomes imperative.

The following inhibition controls, which have been in use in this laboratory for some time, are proposed because they seem to parallel most closely the actual germicidal test.

A. The Drug Transfer—Let it be assumed, for example, that in the actual test the amount of drug employed is 5 c.c., the amount of inoculum 0.5 c.c. of a broth culture, the amount carried over to sub-culture one 4 mm. loopful of this drug-inoculum mixture, and that the amount of broth in the sub-culture is 10 c.c. Under these conditions, the following control should be made:

1. Mix 5 c.c. of the drug dilution to be tested with 0.5 c.c. of sterile broth, the latter corresponding to the amount of the inoculum in the actual test.

2. Transfer one 4 mm. loopful of this mixture to 10 c.c. of broth.

This gives in the sub-culture tube an exact parallel of the amount of drug which is carried over in the actual germicidal test.

B. The Inoculum—Some authors have contented themselves with inoculating their inhibition controls with a loopful of undiluted culture, and others have deemed it sufficient to inoculate their sterile sub-cultures from the actual germicidal tests, some 48 or more hours after the test. Such inoculations usually have been with undiluted cultures. Both of these methods are fallacious. Under the conditions cited above, the correct inoculation of the inhibition control should be made as follows:

1. Mix 5 c.c. of sterile water with 0.5 c.c. of the same tube of culture that is used in the germicidal test, and at the same time as the actual test.

2. Transfer one 4 mm. loopful of this mixture to 10 c.c. of broth in which has previously been placed one 4 mm. loopful of the drug-water mixture described under "A. The Drug Transfer."

This inoculum represents the maximum number of organisms that could

possibly be carried over to the sub-culture in the actual test. No inhibition controls which employ any larger number of organisms are valid. In fact, the point may well be made that it is not fair to use even this maximum number of possible organisms, as this method does not take into account the reduction of the maximum number by drug action in the actual test. By making culture dilution controls the exact point at which sub-cultures remain sterile, owing simply to the small number of bacteria present in the 5.5 c.c. of the test mixture, may be determined. It seems probable, however, that, without working with fractions of the maximum number of organisms, the controls outlined above are sufficiently refined.

It is obvious that this inhibition control may be expressed as a formula for use with any method.

Let D represent the number of c.c. of drug employed in the test.

Let B represent the amount of inoculum employed.

Let S represent the amount of the mixture of D plus B used for sub-culture.

Let T represent the number of c.c. of broth used for sub-culture.

The inhibition control then consists of the following steps:

1. Mix 1 D and an amount of sterile broth equal to 1 B.
2. Transfer the equivalent of 1 S of this mixture to 1 T.
3. Mix the equivalent in sterile water of 1 D with 1 B.
4. Transfer the equivalent of 1 S of this mixture to the 1 T previously used in the second step.

Such inhibition controls should be made with every dilution of drug employed and with every type of organism used. It is wise to run such controls in triplicate to allow for unavoidable experimental variation.

The author realizes that these controls must either be accepted by others as they stand or modified according to the consensus of opinion of other workers in this field. However, these or essentially similar inhibition controls must be included before germicidal tests can be considered valid. Certainly the importance of such inhibition controls cannot be too strongly emphasized.

SUMMARY

A method of making inhibition controls has been proposed by which valid germicidal tests may be made by any accepted method.

A MODIFICATION OF THE SEITZ 20 ML. FILTER

N. W. LARKUM, PH.D.

Michigan Department of Health, Lansing, Mich.

THE advantages of the Seitz filter over many other types have been presented at length by the writer.¹ In the hands of many workers, however, results were not always satisfactory owing to a tendency on the part of such filters to leak air around the edges of the filter pad. This, of course, resulted in contamination of the filtrate. Air leakage is entirely avoidable pro-

vided a tight seal can be assured. With the type of filter at present on the market, pressure on the disc is secured by screwing down a threaded cylinder having a diameter of 44 mm. The base has the same diameter. Both top and base have a knurled flange which is 2 mm. thick. It is very difficult to secure a grip on these filters sufficiently firm to give the pressure necessary for a

tight joint. Further, the thinness of the flange makes the operation at times rather hard on the hands. By increasing the width of the flange it is possible to secure a better grip. By increasing the diameter of the cylinder more leverage can be obtained. The combination of wider and thicker flanges makes possible the application of much more pressure and assures an adequate seal. We have made a number of these filters and have found that in addition to much greater ease in assembling there have been no air leaks in any of our tests even when the pressure was greatly increased over that we had previously been using. One of the chief objections to the Seitz filter was the inability to secure sterile filtrates due to this leakage. It is felt that with the modification this objection has now been met.

An illustration showing the old and the new types is appended to show the differences between the two.

VITAL STATISTICS

LOUIS I. DUBLIN, PH. D.

Vital Statistics for Edinburgh, Scotland—One of the interesting facts disclosed by the annual report for 1929 is that for one year at least the population of Edinburgh has decreased. The present number is 427,538. This is 916 lower than it was in 1928. The present situation is accounted for largely by the birth rate, which was the lowest since 1918. At the same time the movement of population due to emigration has also been a contributing factor. Two hundred years ago the population was 40,000. The increase has been slow and steady. Expansion has been mainly due to extension of the city

boundaries. The latest was in 1921 when the population rose from 314,193 to 420,264. While the total population has decreased, there were, in 1929, 1,379 more inhabited houses in the city than in 1928. This is due to new housing schemes and modern ideas of health. There is a tendency to move to more suburban areas.

Edinburgh's birth rate of 17.1 for 1929 is the lowest rate among the 8 largest towns in Scotland. At the same time, the death rate has increased to 15.1, the highest since 1922. The infant mortality rate is 80.—*Canad. M. A. J.*, 23: 854 (Dec.), 1930.

Vital Statistics for Vienna, Austria—The population for Vienna at the end of July, 1930, has been announced as 1,843,759, consisting of 850,733 males and 993,026 females. In July there were 260 fewer living births than in the previous month; only 296 of these births occurred in the home; the remaining 1,149 took place in institutions. The total number of deaths in July was 1,854 or 179 fewer than the previous month.

At the end of 1929, the population of Vienna was reported as 1,848,147, which is almost 30 per cent of the whole population of the republic. The total number of deaths for 1929 was 26,682, of which 1,044 were due to suicide and 75 to homicide. The chief cause of death was diseases of the heart and circulatory organs; cancer and neoplasms occupied second place and tuberculosis came third. Of the infectious diseases, diphtheria showed a high incidence; then came puerperal fever, typhoid, scarlet fever, measles and whooping cough. Not a case of Asiatic cholera, typhus or smallpox was reported in Vienna during 1928 and 1929.—*J. A. M. A.*, 95: 1985 (Dec. 27), 1930.

Diphtheria Immunity—Schick tests were made on 883 children in a small community, Rochester, Minn., with a population of about 20,000. The children ranged from 1 to 18 years of age. There were 411 of these children who had not been subjected to measures of diphtheria immunization and whose tonsils had not been removed. In this group there were 99 children under 6 years of age, 4 of whom showed negative reactions. Two of them had previously had diphtheria. Of the group from 6 to 18 years, 312 in number, 52 or 16.6 per cent gave negative reactions. In the group as a whole, 13.6 per cent of the Schick tests gave negative results.

In the second group were 96 children

who had been tonsillectomized more than 6 months previously but had never been immunized against diphtheria. Nineteen were under 7 years of age and all gave positive results. Of the 77 between 7 and 18 years of age, 20 or 25.9 per cent gave negative reactions. In this group as a whole 20.8 per cent gave negative reactions.

In the third group were 24 children who had received toxin-antitoxin or toxoid and who had not had their tonsils removed. There were 32 under 5 years of age and all gave negative reactions. Of the 209 children between 5 and 18 years, 153 or 73.2 per cent gave negative reactions. The group as a whole showed 76.7 per cent negative reactions.

The last group was made up of 135 children who had received toxoid or toxin-antitoxin and whose tonsils had been removed more than 6 months previously. All of these children were between 5 and 18 years of age; 101 or 74.8 per cent of them gave negative reactions.

These results indicate that tonsillectomy had no effect on humoral immunity against diphtheria in this small community. The number of tests in this case was too small to allow accurate deductions, however. There have been only 30 cases of diphtheria in Rochester in the last 5 years; of these 7 cases were definitely imported and resulted in 3 secondary cases.—K. B. Geddie, Effect of Tonsillectomy and Adenoidectomy on Diphtheria Immunity. *Am. J. Dis. Child.*, 40: 1032-1034 (Nov.), 1930.

Pneumococcus Type I Pneumonia—A series of 3,662 cases of pneumococcus pneumonia in adults and 271 cases in children admitted to Bellevue Hospital for the past 10 years was studied clinically and bacteriologically. Of this series, there were 1,161 cases of type I infections and these form the basis for this investigation. The most

serious complications among the 1,131 adults were empyema, 73 or 6.5 per cent; meningitis, 20 or 1.8 per cent; and acute arthritis, 10 or 0.9 per cent. The common complications in the 30 children were empyema and otitis media, each of which occurred in 5 cases.

In the period from 1920 to 1929, in the series of 412 cases not given serum, there was a mortality of 28.2 per cent. The death rate for type I pneumonia in Bellevue Hospital has shown a steady rise since 1921. In the period from 1921 to 1929, the mortality rate increased from 20 per cent to 42.8 per cent. The mortality rate varied with the age of the patients; in children under 12 years old, it was 3.3 per cent; each decade the rate was higher and in patients over 50 it was 46.2 per cent. The mortality rate in patients with serious complications was very high; 29 cases of pneumococcus type I empyema showed a death rate of 51.7 per cent.

Huntoon's antibody solution was given to 171 cases of type I pneumonia for two years, 1920 to 1922. There was a death rate of 14 per cent; 171 control cases admitted during the same period showed a death rate of 21.1 per cent. In 56 cases admitted within 48 hours after onset, treatment with antibody solution resulted in a death rate of only 8.9 per cent, whereas 68 control cases showed a death rate of 23.5 per cent.

From 1924 to 1929, alternate cases of type I pneumonia were treated with Felton's concentrated antipneumococcus serum. There were 239 cases treated with a death rate of 20.1 per cent; 234 alternate controls showed a death rate of 31.2 per cent. In this 4-year period, the death rate of the treated cases varied from 17.7 to 22.9 and for the controls from 26.3 to 39.4 per cent. There was a further reduction in the death rate to 11.7 per cent in cases treated within 72 hours after onset as

compared with a rate of 26.8 per cent for 97 controls. There were 48 deaths among the patients treated with Felton's serum but some morbid process other than pneumonia was a factor in nearly every case.—R. L. Cecil and N. Plummer, *J. A. M. A.*, 95: 1547-1553 (Nov. 22), 1930.

Tuberculous Infection in School Children—This study is based on 42,071 children examined and given the Pirquet tuberculin test during a period of 3 years. These are the results of the beginning of a 10-year program begun in Massachusetts in 1924 to find children who had the primary or juvenile form of tuberculosis. Since the study of the cases examined during the first 3 years' work in the clinics, 2 more years' work has been added. During the 5 years, there were 101,118 children given a tuberculin test and the positive reactors X-rayed. Twenty-eight per cent of the children gave positive reactions during this period.

Different sections in the same city showed a wide variation in the percentage of reactors. In one city of 60,000, the number of children in different school districts reacting to the tuberculin test varied from 11 per cent to 60 per cent. In the 3 junior high schools in this city, there were 22, 26 and 26 per cent reactors, respectively. In 8 schools, the children in the first six grades had a much higher percentage of reactors than the older children.

A study of children by the nativity of mothers showed no marked variation in the number of reactors when there was no history of contact. This study showed that approximately twice the number of children react to the tuberculin test when there is a history of exposure to pulmonary tuberculosis. The Teuton group showed 3 times as many reactors in the contacts. The Teuton non-contact group, 533 in number, showed only an average number

of reactors. The percentage of acknowledged contacts in each group ranged from 11 to 19 per cent. The highest percentage of contacts and the highest percentage of infections were shown for the Latin group.

Irish, Canadian and German boys showed a much higher incidence of infection than girls of the same nationalities. The reactors among the boys exceeded the girl reactors by more than 24 per cent in the Irish group, 50 per cent in the Canadian group and 52 per cent in the Teutons. In other nationalities, the percentage of reactors in the two sexes was approximately the same.

Comparing the results of the tuberculin survey made in 1917 by the Framingham Demonstration and the one made in the same city in 1926 by the State Clinic, a marked reduction in tuberculous infection after 9 years of intensive antituberculosis work was shown. The children in the 1926 group averaged 5.7 years older than those examined in 1917 but the percentage of reactors was 8.5 per cent less. The numbers considered in this comparison are small, but the marked reduction in infection checks up with the reduced death rate in Massachusetts for all forms of tuberculosis, which declined from 144 per 100,000 in 1917 to 73 in 1927.—H. D. Chadwick and D. Zacks, *The Incidence of Tuberculous Infection in School Children*, *Tubercle*, 12: 111–118 (Dec.), 1930.

The Future of the Diabetic Child
—A series of 625 diabetic children treated from 1898 to 1930 formed the basis for this study. Of these children, 212 are dead and 413 living. The series contains many patients in whom a variety of methods of treatment has been employed. In order to compare the data fairly, the living children were divided into two groups, 81 children treated before the use of insulin was

begun and 332 treated subsequently.

The skin of some of the children of both groups has shown xanthosis. *Xanthoma diabeticorum* has proved a rare complication, being recognized in only 3 cases. Tuberculosis or tuberculous lesions have occurred in 10 of the total 625 children, in 7 whose diabetes began before 1922 and in 3 whose onset was after that date. Only one child has cataracts. However, 3 of the fatal children who had never had insulin had cataracts.

Calcification of the blood vessels of the legs has occurred in 11 diabetic children, all of whom had onset of diabetes before 1922. The average duration of diabetes at discovery of sclerosis was 7 years. In 5 of these children the cholesterol of the blood was examined prior to the appearance of sclerosis; in 2 the cholesterol was above 230 mg.; in 3 it was persistently below. The average proportion of cholesterol in the group was 212 mg. per 100 c.c.

The children in this group with the longest duration of treatment are children treated by Dr. Joslin in the Allen era with few calories and relatively low quantities of carbohydrate. These children gained tolerance for carbohydrate. This treatment kept alive 50 diabetic children whereas children treated by other methods died. Insulin has been used 7 years by 59 diabetic children in this group. None of these have shown evidence of sclerosis whereas 3 of the pre-insulin children studied had evidence of calcification of the vessels of the legs.

The diabetic child has taught lessons of great importance: first, that heredity is an undoubted etiologic factor in diabetes; second, that the child affords new evidence to the theory that over-nutrition is a precursor of diabetes; and third, that cataracts and arteriosclerosis can occur in pure diabetes under the age of 20 years.—P. White, *J. A. M. A.*, 95: 1161–1162 (Oct. 18), 1930.

PUBLIC HEALTH ENGINEERING

ARTHUR P. MILLER, C. E.

EPIDEMIC OF INTESTINAL DISORDERS IN CHARLESTON, W. VA., OCCURRING SIMULTANEOUSLY WITH UN- PRECEDENTED WATER SUPPLY CONDITIONS

E. S. TISDALE

Director, Division of Sanitary Engineering,

West Virginia State Department of Health, Charleston, W. Va.

THE great drought of 1930 caused public water supply conditions in Charleston, W. Va., from August to December, 1930, which probably have never been duplicated in a public drinking water supply for intensity of pollution. A widespread epidemic of intestinal disorders similar to those caused by mild food infection or a strong cathartic occurred in the city during the latter part of October and early November in which it was estimated that between 8,000 and 10,000 persons in Charleston were affected.

Throughout the entire period of 4 months—August to December, 1930—in which the acute and offensive taste and odor conditions existed in the water supply and a high pollution thereof continued due to a river reversing its flow, the filtration plant operation was above reproach, and daily independent bacteriological tests by three different water testing laboratories showed that the U. S. Treasury Standards for a bacteriologically safe drinking water had been met.

Charleston is furnished its public water supply of approximately 7 m.g.d. by a private water company, the source being the Elk River. This river with a 1,550 sq. mi. drainage area and a normal flow of 100 to 500 m.g.d. joins the canalized and navigable Kanawha River

1¼ miles below the water supply intake. Previous low water flow in the Elk over a period of 50 years was 19 sec. ft. Below the water intake are many sewers and a garbage incinerator which, due to laxity on the city's part during 1929 and until July 24, 1930, was discharging weekly 200 tons of household garbage and wholesale produce to the river. The State Water Commission, which has authority over stream pollution, ordered this grossly insanitary practice of discharging garbage into the stream stopped on July 24, 1930, and the city complied immediately.

Early in August the Elk River flow fell below the city's needs to the extent of 2 or 3 m.g.d., and then the Kanawha River, carrying the excessively high organic content from garbage putrefaction, with practically zero dissolved oxygen, and so polluted with sewage as to give a bacteria count of 50,000 to 100,000 per c.c. and *B. Coli* in 1/1,000 c.c., flowed upstream to the water intake. A heavy growth of algae developed in this filthy pool into which only a few million gallons of fresh water entered daily and a woody, mouldy, disagreeable taste developed with which strenuous water purification methods could not cope.

The following purification measures.

in addition to the regular sedimentation, filtration and final chlorination processes, were tried: prechlorination to reduce the heavy pollution load, using copper sulphate in the river basin to kill algae; aeration to attempt to replace the dissolved oxygen; and activated carbon fed into the inlet to the sedimentation basin to absorb the disagreeable flavors. Permanganate, ammonia, super-chlorination and dechlorination treatments also were tried in an effort to get rid of tastes and odors. All these measures were ineffective in removing entirely the taste and odor which came and went in varying intensity.

The prechlorination dosage finally reached a peak of 20 lbs. per m.g. The daily operation throughout August, September, October and November was under the watchful eyes of capable sanitary engineers. Every effort was made to see that no unsafe water passed into the city mains. Bacteriological tests indicate that, measured by the present accepted U. S. Treasury Standards for bacteria content, the water was safe.

Microscopical tests during August and September revealed a b u n d a n t growths of blue-green algae of several different types capable of causing the objectionable odor. Cycles of algae growth were followed by development of crustacea, daphnia and other allied water flea organisms being present in such great numbers that a glassful of the raw river water appeared to be actively vibrating from the infinite number of organisms present.

So intense and disagreeable was the taste, particularly in the latter part of October and in early November, that, naturally, the general public refused to use the water for drinking purposes.

The State Health Department, relying upon the standardized bacteriological tests as a criterion for safe water, urged the general public to use the purified public supply rather than that from unknown wells and springs, or bottled

waters which were being widely dispensed throughout the city for beverage purposes. The concentration of bacterial pollution of the lower Elk River pool, made up of both Kanawha River and Elk River waters, increased proportionally as the weeks went on because the Elk River practically dried up. Prechlorination had become the normal operation now in order to put out a safe water, a residual chlorine being held throughout the sedimentation basin, the filters and clear well.

Whether the intestinal disorders in the city during the latter part of October and in early November can be attributed to the water is still a mystery; but it is a fact that widespread disorders were noted wherever the water supply mains went. After careful epidemiological studies had been made by state and federal public health agencies, it was recommended that the intake be moved to the Kanawha River to a less sewage polluted zone. The water company is now spending \$100,000 to install such an emergency intake.

On November 10 Dr. W. T. Henshaw, Commissioner of the State Department of Health, following a report to him by Dr. David Littlejohn, his epidemiologist, and E. S. Tisdale, state sanitary engineer, that several thousand cases of an acute intestinal ailment existed in Charleston, communicated with Surgeon General Hugh S. Cumming of the U. S. Public Health Service, stating the unusual conditions and asking assistance to determine if possible the real cause of the trouble. The Service immediately complied and Surgeon M. V. Veldee and Sanitary Engineer R. E. Tarbett arrived in Charleston on Armistice Day. They spent 3 days reviewing carefully the findings of the State Health Department, going over the bacteriological records, and making independent epidemiological studies. Their report describes the type of ailment from which Charleston people suffered:

A house-to-house canvas of a fair group of families living in two widely separated sections of the city reveals that from 10 to 15 per cent of the population was ill during the first week of November with an acute gastrointestinal ailment. This illness was characterized by a sudden onset, pain in the region of the stomach, usually nausea or vomiting or both, and followed by diarrhea of varying severity. Those ill had essentially no fever and the illness was very largely confined to persons over 10 years of age. The duration of illness varied with severity—usually from less than 1 day to upwards of 4 days.

In addition an interview was had with a representative group of the local physicians. The symptoms observed by them among their patients correspond with those recorded above.

The character of the onset and the ensuing symptoms do not suggest a disease caused by a bacterial infection but rather a poisoning by some substance which acts as a gastrointestinal irritant. In fact, the symptoms are similar to those produced by a strong cathartic.

In the case of the local source of water supply, the quiescent condition of the pool has allowed anaerobic decomposition (fermentation in the absence of oxygen) to take place in the accumulated sludge, with the absorption of the products of decomposition by the overlying water to an extent not possible in a flowing stream. It is entirely possible that such products might not be removed by the known processes of water purification.

In so far as we are aware the circumstances surrounding the public water supply of Charleston at the present time are entirely unprecedented in this country. In view of this fact we do not feel that the occurrence of an outbreak such as has taken place in Charleston within the past few weeks could have been reasonably predicted, particularly since the bacteriological records continued to indicate a drinking water of safe quality.

DEDUCTIONS FROM UNUSUAL CONDITIONS AT CHARLESTON, W. VA.

It is of note that the Charleston malady affecting several thousand people was experienced during unusual drought conditions. Actual septic conditions similar to those found in a septic tank prevailed in Elk River near the water works intake due to decomposing garbage, and sludge from the sedimentation

basin, lying on the river bottom. Violent ebullition of bubbles took place when this river bottom sludge was disturbed. River traffic—stern wheel paddle-boat variety—was quite active in this stretch of river.

Whether products of anaerobic decomposition of nitrogenous or carbonaceous matter could be sufficiently concentrated in the water to produce a condition simulating food poisoning in those drinking the water has not been shown. Laboratory tests did show that the odoriferous compounds were quite readily removed by boiling and there appeared to be a large amount of oily substances in the water.

It is of interest to note that *Public Health Reports* of November 21, 1930, give an account of R. R. Spencer's studies of a persistent type of mild dysentery-like epidemic occurring in the national parks during the drought months of the year. His description of the malady (short duration, nausea, sharp pain in abdomen and diarrhea) is similar to the trouble which occurred in Charleston when drought conditions were at their height.

Neither the U. S. Public Health Service nor the State Health Department has stated definitely that the bacteriologically safe water supply was responsible for the epidemic, but it is certain that most unusual conditions have existed with reference to intensity of raw water pollution. The recommendations which both federal and state services have made were to the effect that

1. Boiling the water would drive off the substances responsible for the objectionable tastes and odors.

2. A temporary intake should be sought in the Kanawha River in a zone of less pollution since the water plant was operating under too great a sewage load.

3. A new water works intake be provided so that 1930 drought conditions could not be duplicated.

INDUSTRIAL HYGIENE

EMERY R. HAYHURST, M. D., PH. D., AND LEONARD GREENBURG,
M. D., PH. D.

Occupational Nystagmus in Train Dispatchers—Summary: Among the 121 train dispatchers examined, in widely separated sections of the country, and from seventeen railroads, occupational nystagmus has been detected, involving 81 individuals, or 67 per cent. In addition, in 2 cities, among 30 persons examined, 22, or 70 per cent, presented this condition.

The nystagmus found was essentially all horizontal, with marked variation in the rate of motion, and with some variation in the rates for the two eyes.

This train dispatchers' nystagmus appears to be unassociated with aural conditions, although occupational deafness of 56.2 per cent has been noted, which is more commonly present in the left ear, due to the wearing of the hearing mechanism on that ear. It is believed that the noises common to train dispatching are responsible for the occupational deafness.

The nystagmus encountered among train dispatchers is accepted as occupational in origin, and is attributed to the continual motion of the large paper train sheet beneath the eyes, and the movement of the head and eyes over the train sheet, both necessary in the continual recording of train movement data.

It is maintained that the high frequency of the use of eyes in connection with train sheet work leads to overworking of the ocular mechanism, resulting in a nervous syndrome characterized by nystagmus, blepharospasm, some visual impairment, and ocular discomfort.

This occupational nystagmus of train dispatchers is less severe than the average of miners' nystagmus, and no case has been encountered that in itself was to be accepted as the cause of total disability.—Carey P. McCord, Paper delivered before the Industrial Hygiene Section of the A. P. H. A. at the Fifty-ninth Annual Meeting at Fort Worth, Tex., October 30, 1930.—E. R. H.

Life Conservation Studies. Cardiovascular Lesions Among One Thousand Industrial Machine Operators. A Report of One Thousand Physical Examinations of Machine Operators—Summary:

1. One thousand machine and hand tool operators were carefully examined during the past year by the Heart Council of Greater Cincinnati.

2. Only 4 of these men were found essentially free from defects; 836 men out of the 1,000 had significant physical defects such as were considered to be likely to interfere with their general well-being and efficiency. The defects were unknown to 885 of the men, or at least they made no complaint of these defects at the time of the examination. In the opinion of the examiners, 874 of the group would definitely profit by early medical care.

3. Men under age 45 predominated in these occupations in Cincinnati.

4. One out of every 5 had never been vaccinated.

5. Thirty-one per cent had some significant cardiovascular defect. There was a definite upward trend in cardiovascular disease among this group after age 40 which corresponds to the mortality from this disease in the United States vital statistics. The incidence of cardiovascular lesions increased markedly with overweight in this group. The increase in the incidence of heart disease among overweight is especially great past the age of 40.

6. Overweights were prone to high blood

pressure; underweights to low blood pressure.

7. Albuminuria and glycosuria are both appreciably more frequent among those with cardiovascular lesions than for this group as a whole.

8. The query is definitely raised as to the relationship between mental strain and cardiovascular lesions in the light of the fact that the incidence of these lesions among this factory group where the mental strain is comparatively slight is less than among 1,000 clerks who work under a higher degree of a mental strain and about one-half as great as that found by McCord in a group of train dispatchers among whom mental strain is excessive.

9. Eighty per cent of these men have dental attention only in emergencies.

10. Three-quarters have some eye defect and a large percentage of the attempts at correction of these defects are unsuccessful.

11. Tuberculosis findings were incomplete because of the difficulty of securing X-ray examinations.

One definite and incontrovertible point brought out in the first two studies is the extraordinarily high incidence of physical impairments, much of which was unknown to the examinees, together with the high percentage of the men with impairments which the examiners believed could be remedied by medical care. The findings add significantly to the accumulating evidence of the importance of periodic health examinations.—William Muhlberg, Floyd Allen, and Bleecker Marquette (Cincinnati). Paper read before the Industrial Hygiene Section of the A. P. H. A. at the Fifty-ninth Annual Meeting at Fort Worth, Tex., October 30, 1930.—E. R. H.

An Industrial Health Survey of 1,000 Factories in Chicago—A simple questionnaire of 15 questions which could be answered by "Yes," "No," or a Figure, was sent to 1,584 factories, mercantile establishments, department stores, banks, laundries and others, the list being supplied from the Directory of the Illinois Manufacturers Association, from the Association of Commerce

and a social agency of Chicago, the aim being to reach all plants with 25 or more employees. From this group, 584 were excluded because of several reasons, leaving 1,000 on which the study was made, or about 16 per cent of the original list.

It was found that: (1) 820, or 82 per cent, of the plants replying had less than 300 employees, and (2) 881, or 88 per cent, had less than 500. All industries in Chicago employing more than 1,000 employees replied to the questionnaire. Among the larger were 54 employing 500-999; 47 employing 1,000-4,999; 8 employing 5,000-9,999; and 10 employing over 10,000. The total employees in the 1,000 institutions were 500,642, of whom 438,948 were classified as to sex, there being 73 per cent male and 27 per cent female.

A survey of health service showed that 3 per cent had a hospital; 5 per cent had a dispensary; 52 per cent had a first aid room—this included any room in which a first aid kit was kept; 43 per cent had a doctor—here the doctor was on call in 82 per cent of instances; 12 per cent had a nurse, but only 72 per cent of these were registered nurses, while 1 per cent employed a part-time nurse; 35 per cent had agreements with local hospitals covering sickness and injuries; 13 per cent had employees' benefit associations; about 100 per cent were covered by compensation insurance; 33⅓ per cent had group life insurance; 49 per cent kept sickness and accident records—15 per cent kept accident records only; while 75 per cent of the plants wanted a report of the survey.

The significant facts revealed in this study were:

1. The medical service provided by Chicago industries is of a limited character as evidenced by the answers to the first five questions, especially in regard to medical and nursing service. The medical and nursing service for the most part is of an emergency character.

2. Adequate health work presumably can only be done by a full-time medical service. Indications of health work were not significant in this study.

3. Plants in Chicago apparently are quite interested in the general welfare of their employees as evidenced by the answers to the balance of the questionnaire.

4. The answers were classified according to size of the plant, but no startling evidence was revealed. For the most part the medical and nursing service is still concentrated in the larger plants, leaving the greater majority of plants without service beyond a strictly emergency character

There is evident tremendous interest in health among the employers and any program contemplated by a tuberculosis

organization should include the large as well as the small plant. An educational program is clearly indicated from the above facts brought out by the survey and steps were taken to provide this service. "We are looking forward to the day when all cities with over 100,000 population will have a program. We in Chicago feel that industrial health, like community health, is purchasable."—Robert B. Watson, Industrial Secretary, Chicago Tuberculosis Institute. Paper read before the Industrial Hygiene Section of the A. P. H. A. at the Fifty-ninth Annual Meeting at Fort Worth, Tex., October 30, 1930.—E. R. H.

FOOD, DRUGS AND NUTRITION

WALTER S. FRISBIE

Biochemical Studies on the Antineuritic Vitamin—As a contribution to the study of the antineuritic vitamin, the authors describe a method of chemical purification which is controlled by the application of physiological test methods previously described by one of the authors (M. I. Smith, *Pub. Health Rep.*, 45 (1930), 116-129). The resulting product was further compared with a small supply of vitamin crystals obtained from Dr. Jansen and made by the Jansen and Donath method. The smallest curative dose of this type of the crystals was found to be 0.04 mg. containing 0.0069 mg. nitrogen. The most highly purified fraction obtained by the authors on the same basis required 0.05 mg. daily dose containing 0.0062 mg. nitrogen, indicating almost identical activity on a nitrogen basis, although the product described here does not crystallize. The vitamin is prepared from fresh brewer's bottom yeast by adsorption on fullers'

earth after removing coagulated protein and insoluble matter. This so-called "activated solid" was further treated in alkali and acid solutions, extracting with chloroform and precipitating the filtered acid aqueous solution in acetone.

Further treatment is outlined for the separation of the sodium chloride, and by repeated precipitation a powder is obtained containing 7 to 11 per cent of nitrogen. The two samples analyzed yielded 0.1 and 3.3 per cent chloride. Several concentrates prepared by this method were administered to rats to cure polyneuritis. The activity of these concentrates ranged from 0.05 to 0.30 mg., the dose required to effect the cure of polyneuritis in rats on a diet adequate with the exception of this antineuritic vitamin.

Experiments were conducted on rats receiving a diet deficient in both the antineuritic and the thermostable vitamin (B₂ or G), and those on a diet deficient in the antineuritic vitamin

alone. After the rats developed polyneuritis symptoms, the autoclaved yeast was replaced by an equivalent amount of starch. The antineuritic concentrate was then administered intravenously in about 20 per cent of the minimal curative dose required. The animals recovered from polyneuritis but did not grow and their death followed in 22-32 days. Increasing the dose 5 to 10 fold prolonged the life of the animals sufficient to show skin lesions. With the daily injection of 1.0 mg. of the antineuritic concentrate to rats with developed polyneuritis and the administration of the thermostable factor normal growth resulted. It was concluded that this concentrate was highly active in antineuritic potency and probably free from the thermostable factor.—Atherton Seidell and Maurice I. Smith, *Pub. Health Rep.*, 45: 3194 (Dec. 26), 1930.

The Antirachitic Action of Cod Liver Oil and Irradiated Ergosterol in Parathyroidectomized and Thymectomized Rats—The observations of investigators who have studied the effect of antirachitic agents in the experimental tetany of dogs and monkeys are at least conflicting, both a loss and an increase in blood calcium being reported, the latter particularly with large doses of irradiated ergosterol.

In the present experiments, young rats, 25-40 gm. were used after complete extirpation of the parathyroids under anesthesia. The rats on a low phosphorus rachitogenic diet were given cod liver oil with a pipette. Radiograms were taken at the beginning and end of the experiments. A commercial irradiated ergosterol claiming a potency 10,000 times that of cod liver oil was diluted with 10,000 parts olive oil and administered by pipette. Consistent results are shown in 4 sets of experiments. Four drops daily of cod liver oil resulted in complete prevention and 4 drops for the last 5 days were a curative dose in

the parathyroidectomized rats. Without the oil, rickets developed in both the untreated operated and unoperated controls. With two drops cod liver oil daily for the last 5 days marked healing occurred in parathyroidectomized rats and also in the unoperated controls.

Similar results attended the experiment using the commercial activated ergosterol and complete prevention in parathyroidectomized rats resulted with a daily dose of 1 drop of the diluted preparation. Marked healing occurred with 5 daily doses of 1 drop of the preparation both in parathyroidectomized rats and in unoperated controls.

The rickets were more severe in the operated than in the control rats. Sections of the neck organs showed that no remains of parathyroid tissue and accessory glands were in evidence. Results are shown in one experiment on rats after complete removal of the thymus glands. Two drops daily of cod liver oil gave complete protection in thymectomized rats as well as the unoperated controls and 5 daily doses of 2 drops showed a marked healing both in the operated and unoperated rats.

One experiment is reported on rats after removal of both thymus and parathyroids and administration of irradiated ergosterol. One drop daily prevented rickets, which developed in the unoperated controls. It is apparent that cod liver oil and activated ergosterol in therapeutic doses are antirachitic in the absence of either or both the parathyroids and the thymus.—Alwin M. Pappenheimer, *J. Exper. Med.*, 52: 805 (Dec. 1), 1930.

Vitamins in Sugarcane Juice and in Some Cane-Juice Products—This paper reports the results of experiments carried out to determine the vitamin B (complex) and vitamin D potency of the juice of sugarcane. The juice was obtained from 3 lots of sugarcane stalks shipped at different times

and from different sections of the country. In addition to estimating the vitamins in the juice, comparison was made of the vitamin B potency of juice obtained from different parts of the same cane stalk. Several sugarcane products, including cane sirup, and different samples of blackstrap molasses and cane cream were also examined.

From the growth curves given for the different experiments, sugarcane juice is found to be a poor source of the antineuritic vitamin. It contains a small amount of vitamin A and little, if any, vitamin D. The juice from the upper portions of cane stalks is richer in this vitamin than juice from the lower portions. Juice obtained from bagasse by using high pressure is richer in the antineuritic vitamin than ordinary cane juice. Cane sirup, Louisiana and Porto Rico blackstrap molasses, and cane cream, products made from sugarcane juice, were found to contain negligible amounts of vitamin B.—E. M. Nelson and D. Breese Jones, *J. Agr. Research*, 41: 749 (Nov. 15), 1930.

The Length of Survival of Paratyphoid Bacilli in Foodstuffs—The experiments reported in this paper are of considerable importance in clarifying the question of the longevity of members of the Salmonella group and their agglutinogens when they are introduced into commercially canned foods, such as spinach, corn, and peas. Several authentic strains of *S. enteriditis* and *S. aertrycke* were used as test organisms. Incubation at room temperature was used throughout the experiments.

Of the three vegetables used canned spinach was found the most favorable medium for growth for all the test organisms. Canned corn proved to be the least suitable medium for growth, especially when inoculated with strains of *S. aertrycke*. No viable organisms could be demonstrated in canned corn which had been inoculated with *S.*

aertrycke after 21 days. In another instance some viable bacilli of this strain were recovered from corn after 75 days. All *aertrycke* organisms were dead after 100 days. Canned corn was somewhat more favorable as a medium for *S. enteriditis*, sterility being observed in from 90 to 170 days.

In canned peas, both organisms lived for at least 200 days. In canned spinach both organisms survived for much longer periods than they did in either corn or peas. In this vegetable, *S. enteriditis* was alive at the end of one year, while *S. aertrycke* was still alive at the end of 3 years. The persistence of the agglutinogens of these organisms in the canned vegetables was determined by the incubation of small amounts of liquor from the cans into rabbits and then testing the rabbits' blood serum for agglutinins. These tests were made 3 years after the canned vegetables were inoculated; during this period the bacilli had died in all cases—except that of *S. aertrycke* in canned spinach. In these tests, the thermostability of the various agglutinogens was observed. The injection of unheated inoculated canned vegetable material gave rise to easily recognizable agglutinins in all cases 3 years after the foods had been inoculated. Relatively slight heat apparently destroyed or greatly reduced the enteriditis agglutinogens. Some thermostability was observed in the case of enteriditis agglutinogens from canned peas.

The *S. aertrycke* agglutinogens were observed to be quite thermostable, giving rise to definite agglutinins when heated material was injected into rabbits. The author found, in other trials, that *S. aertrycke* agglutinogens withstood autoclaving at 11 lb. pressure for 50 minutes. These observations are important as bearing on the possibility of detecting dead organisms of this group in heat preserved foods.—L. P. Doyle, *J. Infect. Dis.*, 47: 92 (Aug.), 1930.

CHILD HYGIENE

RICHARD A. BOLT, M. D., DR. P. H.

Racial Hygiene—It is quite evident that if any further decided reduction in infant mortality is to be effected it must be brought about by applying well known social, medical and hygienic principles to the prenatal, natal, and neonatal periods. Unquestionably, greater safeguards thrown about the prospective mother and more skilled attention at childbirth will preserve more infant lives and reduce considerably the risks to which both mother and babe are exposed. This, of course, will not affect appreciably the quality of those who survive. Why should this interest the health officer? Keeping down the morbidity and mortality rates is conceived to be his duty; he should not wander into the occult and controversial fields of heredity and eugenics. Does not the pasture of eugenics provide sufficient room for his exercise?

But the progressive health officer, interested in the broad field of child welfare, cannot overlook the problems of racial hygiene. Efforts toward conservation of children, communicable disease control, or development of more vigorous life meet at the threshold factors emerging from inherent defects of the individual, differing degrees of intelligence, and constitutional weaknesses. Whether he acknowledges these differences or not the public health officer comes face to face with them in his everyday dealings with enfeebled stock. Questions must arise regarding differential birth rates, feeble-mindedness, and the impoverishment of germinal plasma with so-called "racial poisons." Sooner or later the health officer will have to make decisions as to how far he feels it necessary to carry

out education along the lines of social hygiene, whether to establish maternity clinics, or to lend his influence to the birth control movement. It seems proper to recommend, therefore, that the health officer inform himself broadly along these lines by reading books and articles from the pens of thoughtful investigators and writers.

A beginning might be made with such a thought provoking book as *Racial Hygiene*, by Thurman B. Rice. This is a very practical discussion of the problems of eugenics and race hygiene, written in an easy, straightforward style. To follow up the subject in some detail the list of references given by Rice might well be used.

Causes of Fetal Death—The suggestion is offered at the very beginning of this child hygiene series because in seeking the reasons for fetal and early infant mortality it is not possible to lay a finger upon the exact cause or causes in many cases. The very careful investigation into the deaths of 300 fetuses conducted by Eardley Holland* is an illustration in point. After exhaustive clinical, pathological, and serological studies, Holland found that in 11 per cent of the cases no definite cause of death could be determined. Other investigators have found that from 10 to 15 per cent of such cases show no evident pathological lesion to account for death.

On the other hand, enough reliable data exist to make possible the assignment of proper causes to many deaths;

* Report on the Causation of Foetal Death. *Reports on Public Health and Medical Subjects*. Ministry of Health of England, No. 7. 1922.

among these are syphilis, the toxemias of pregnancy, complications of labor, prematurity, and diseased fetal and maternal states. Great concern is manifest at present in the preventability of fetal and early infant deaths so intimately involving the life of the mother.

One of the most informative and constructive reports at the recent White House Conference was that on maternal and early infant care. It showed clearly the need for more precision in diagnosis and better classification of these cases; for better obstetrical education, and control of midwifery; for more widespread prenatal care of a thorough type, and especially for more-skilled attention at time of birth, under favorable conditions, and with expert care for the new-born. This report naturally arouses inquiry as to how successful prenatal care has been in the reduction of maternal and early infant mortality.

Value of Prenatal Service—This can be answered best by the most outstanding continuous maternity care conducted in this country—the Maternity Center Association of New York. This association has carried out an intensive piece of work in New York City since 1922, and has kept such records that it is now possible to evaluate results in terms of mothers' and babies' lives saved. The routines established by this organization and the "Standards for Maternity Care" which it has set up have been taken as models throughout the country.

"A Recent Statistical Study of Maternity Care," by Louis I. Dublin and Hazel Corbin, appeared in the *American Journal of Obstetrics and Gynecology* for December, 1930. It points out that during the past 8 years the Maternity Center Association cared for 4,726 cases. Of this number, 28 per cent first came under observation before the 5th month of pregnancy; 34 per cent in the 5th or

6th month, and 38 per cent during the last 3 months of pregnancy. The following results are of particular interest:

1. During the entire period of 8 years no woman under care died before confinement.

2. Eleven mothers died after delivery from puerperal causes, making a rate of 2.2 per 1,000 live births, which may be compared with a total rate of 5.3 maternal deaths per 1,000 live births among white women in New York City. A more striking comparison can be made in the Bellevue-Yorkville district with the mothers who did not have the care of the association; a rate of 6.2 is shown which is nearly 3 times as high as for the mothers who had care in the same district.

3. There were 4,596 live-born babies, 123 stillbirths, and 132 live babies died before reaching 1 month of age.

4. There were 274 premature deliveries, 61 of which were miscarriages. The stillbirth rate was 26 per 1,000 births, which compares very favorably with the total rate for white babies in New York City in 1928, 50 per 1,000 births. The number of stillbirths was 42 per cent lower in the association group than in the rest of the district.

The neonatal mortality rate (under 1 month) was 28.7 per 1,000 live births. This was only one-third of the rate (42.9) for the rest of the Bellevue-Yorkville District.

It is impossible to escape the conviction that this work "demonstrates that, on the score of all essential indexes, prenatal care, as conducted by the Maternity Center Association, produces results."

There comes from an entirely different quarter a report which emphasizes the importance of prenatal care combined with good hospital care, or care in the homes. Sir Arthur Newsholme, writing in the *Quarterly Bulletin* of the Milbank Memorial Fund for July, 1930, gives an instance of exceptionally low maternal mortality for patients looked after by the East End Maternity Hospital of London. The maternal mortality of hospital patients over a series of years was remarkably low, being in 1921-1926 only 1.1 per 1,000 live births; from 1927 to 1928, 1.19, while the rate for patients delivered in their own homes was lower still, being 0.29

in 1921-1926, and zero in 1927-1928. Sir Arthur states, "there can be no question as to the importance of the rigidly required and cheerfully accepted antenatal supervision" in addition to the quality of the hospital work both in the hospital and among its out-patients.

More Exact Classification—One of the most enlightening studies available is a recent publication of the Health Organization of the League of Nations. It appears as a "Memorandum relating to the Enquiries into the Causes and Prevention of Stillbirths and Mortality during the First Year of Life," and covers studies made by means of a uniform inquiry form and uniform instructions to investigators in Austria, France, Germany, Great Britain, Italy, the Netherlands, and Norway. A definite attempt was made to secure data in such a form as to be comparable between various countries. To this end "Nomenclatures of the Diseases Common to the First Year of Life and the Causes of Stillbirths" are set forth. A decided step in advance toward better classification is given under "Definition of Dead Births," which it is thought of sufficient importance to quote here:

The word "birth" means the separation and extrusion of a foetus from the body of the parturient woman. The birth is to be deemed complete at the instant when the whole of the body of the foetus—head, trunk and limbs—is outside the body of the mother.

The birth is to be deemed a live birth if after birth (as defined above) the infant breathes.

The act of respiration is incontrovertible evidence of life, and its continued absence is to be taken as proof of foetal death.

It is desirable, for statistical purposes, that a distinction should be made between the birth of a foetus which can normally be expected to be capable of existence independent of its mother and the expulsion of one which cannot—births in the latter category being regarded as miscarriages (abortions).

A foetus capable of an independent existence is a "viable foetus" and is the product of a gestation which has lasted at least 28 weeks. Such a foetus will normally measure at least 35 centimeters from the crown of the head to the base of the heel, the body being fully extended. The Committee is of opinion that the latter criterion is the more trustworthy.

Hence a "dead birth" is the birth of a foetus, after 28 weeks' pregnancy, in which pulmonary respiration does not occur; such a foetus may die either: (a) before; (b) during; or (c) after birth, but before it has breathed.

Such a revision in the classification of causes of maternal and fetal deaths as would make possible not only more exact determination of the causes of death, but also an indication of preventability, is to be welcomed. An advance in this direction appears in the recently revised International Classification of Causes of Death. It follows closely that used by Dr. Guilfooy in New York State, and is here presented:

- XI.* Deaths from Diseases of Pregnancy, Childbirth and the Puerperal State
 - 140 Abortion with septic conditions
 - 141 Abortion without mention of septic condition (to include hemorrhage)
 - 142 Ectopic gestation
 - 143 Other accidents of pregnancy (not to include hemorrhage)
 - 144 Puerperal hemorrhage:
 - (a) Placenta previa
 - (b) Other hemorrhage
 - 145 Puerperal septicemia (not specified as due to abortion):
 - (a) Puerperal septicemia and pyemia
 - (b) Puerperal tetanus
 - 146 Puerperal albuminuria and eclampsia
 - 147 Other toxemias of pregnancy
 - 148 Puerperal phlegmasia alba dolens, embolus, sudden death (not specified as septic)
 - 149 Other accidents of childbirth:
 - (a) Caesarean operation
 - (b) Others
 - 150 Other and unspecified conditions of the puerperal state

PUBLIC HEALTH NURSING

EVA F. MACDOUGALL, R. N.*

Concerted Action in Baltimore— According to the standard curriculum, public health lectures to student nurses constitute a required course in Maryland and have to be given by persons experienced in public health work. In 1925 the superintendents of 14 hospitals conducting nursing schools in Baltimore were invited to try out a plan to send all their nurses to one central gathering place where one series of public health lectures could be given to all, saving time and money which might otherwise have been expended in getting lecturers for each of the 14 hospitals.

In the fall of 1925 the first course, arranged by the Baltimore Health Department, was given. It consisted of 10 lectures given by officials chosen from the city health department, the Johns Hopkins School of Hygiene and the Maryland State Department of Health. Ten of the 14 schools invited sent their pupil nurses to these lectures and examinations were given at each hospital at the completion of the course.

The following year student nurses from all 14 hospitals participated, the lectures were increased to 12 hours, and a demonstration visit to the city health department was given. One college credit was given for this 15 hours' work.

The enrollment of nurses increased from 214 from 10 hospitals in 1925 to 356 nurses from 13 hospitals in 1930. (One hospital had closed after 1927.)

The conducting of these lectures is desirable not only because the lectures enable the hospital training schools to meet the standard re-

quirements but because they will in the course of time give all of the graduate nurses trained in the city a better knowledge of preventive medicine and an interest in the health work of the community.—

V. L. Ellicott, M.D., *Baltimore Health News*, Dec., 1930, p. 78.

The Teacher's Morning Inspection in Communicable Disease Control—The school nurse has come to realize more and more the important rôle routine morning inspections play in preventing the spread of communicable disease in her schools. In many instances, she is fortunate enough to have the classroom teacher assume this responsibility, and as a rule the results are most gratifying.

However, how well equipped is our average school teacher to detect symptoms of a communicable disease? A field supervisor in Indiana had a very enlightening experience a few weeks ago. A city school nurse was very much concerned because of a threatened scarlet fever epidemic in one of her schools. Upon inquiry, the supervisor learned that the teachers were giving daily inspections in order to weed out suspicious cases. Fine! but to her great surprise she found that one teacher's idea of symptoms of scarlet fever was "peeling hands and chest"—and every morning she diligently searched for "peeling hands." The school nurse was just as surprised as the supervisor; she had been quite sure that the teachers knew what to look for.

The average lay person has very little, if any, scientific knowledge of communicable diseases and it is up to us as

* Please send printed matter or other material relating to public health nursing to Eva F. MacDougall, 126 State House Annex, Indianapolis, Ind.

public health nurses to spread the light of the essential facts, at least, to as many people as we can. That is part of our preventive program. The majority of teachers are interested in the more commonly known communicable diseases and they will show great interest in the particular disease one of their own pupils may have developed. So—at least while the iron is hot, we should strike. If there is a case of scarlet fever, diphtheria or measles in our schools we should use that unfortunate incident as a golden opportunity to inform the teachers how scarlet fever, diphtheria or measles is spread. We should give a “demonstration inspection”—pointing out some of the definite symptoms—if there are any; and a talk to the students—whether in the 1st or 12th grade—should help the children and grown ups, too, toward developing a more sane and intelligent attitude toward the dreaded “catching sicknesses.”—Henrietta Landau.

A Census of Nurses in Industry—
In 1928 the National Organization for Public Health Nursing sent questionnaires to 2,200 industrial establishments located in all but 7 states of this country and in Hawaii. Information was received from 1,006 of these establishments employing 2,022 nurses. The following are some of the facts obtained:

1. The number of employees in the 24 different types of industrial and commercial concerns ranged from fewer than 250 to more than 10,000.

2. Eighty-five per cent of the total 2,022 nurses were registered nurses.

3. Practical nurses were found in 5 per cent of the establishments reporting, most of which had fewer than 1,000 employees.

4. Only 4 per cent of the total number of nurses were employed part time.

5. Establishments having 2,000 or more employees tended to employ full-time physicians, while those having 1,000 employees or fewer usually had physicians on call.

6. The great majority of nurses in half the establishments were professionally responsible to a physician.

7. The nurses in less than one-third of the establishments had standing orders.

8. Three-fifths of the establishments had nurses working inside only; some had nurses who visited the homes of employees, also.

9. Practically all the nurses gave emergency treatment of injuries and sickness. In descending order of frequency they gave the following services: (1) assisting the doctor in physical examinations, (2) health instruction to employees, (3) participation in safety program, (4) sanitary inspection of plant, (5) nurse examination (inspection) of employees, (6) assisting the dentist.

Routine visiting of absentee employees, usually those known or suspected to be sick, was the most common service rendered in the home.

In some establishments nurses gave health instruction in employees' families.

Comparative working hours of public health nurses:

Health Departments.....	44.7 hours per week
Boards of Education.....	39.7 hours per week
Public Health Nursing	
Associations	47.3 hours per week
Industrial and Commercial Concerns	48.8 hours per week

Louise M. Tattershall, Nurses in Commerce and Industry, *Pub. Health Nurse*, XXII, 12: 636-637 (Dec.), 1930.

EDUCATION AND PUBLICITY

EVART G. ROUTZAHN*

Are You "First" in Anything?—It is worth while to dig out the facts about the rank of your city or state in any phase of public health, especially if you have first place or even second or third; and then to check up to see if you have kept in the van of those who followed your wise example. You can use this information in writing and speaking, when timely, and in planning an anniversary or award of honor.

In *Better Times*, 151 Fifth Ave., New York, N. Y. (Jan. 5, 1931), a correspondent names the following "firsts" for Massachusetts: State Board of Health, State Tuberculosis Hospital, Clinics for Detection of Tuberculosis in School Children, State Cancer Hospital, State Mental Hygiene Clinics, State Hospital School of Crippled Children, State Requirement for Medical Inspection of School Children.

"The Foe of Youth"—This will be the theme of the "Early Diagnosis Campaign" by tuberculosis and other participating health organizations during April, 1931. Better and better is the assortment of about 30 items of campaign material, descriptions or samples of which will be supplied by the various state tuberculosis associations, or the National Tuberculosis Association, 370 7th Ave., New York, N. Y. Folders, booklets, posters, lantern slides, motion pictures (standard and narrow gauge), and electrotypes are offered, in addition to considerable national pub-

licity. Especially good are the two-color letterhead and the 8-page pamphlet on "Laennec the Listener," the story of the stethoscope and its inventor.

It is a campaign for and by health departments and other health agencies, backed by many types of non-health organizations. The campaign is focused by tuberculosis groups which have created the opportunity.

Should not every health agency scrutinize carefully the material and plans to determine its own share in this opportunity?

Getting Together on Health Education—In 14 cities and states there are social work publicity councils. All of them include groups of health workers. In a score of cities there are small groups of members of the Public Health Education Section.

Why not a get-together session? Is there not enough material—are there not enough topics—in this issue of the *Journal* to talk about? Try it just once.

For further suggestions write to the editor.

"Keeping Up with the Joneses"
Who Edit Magazines—"It takes all the running you can do to keep in the same place," is quoted by Arthur Dunham in a spritely article on "The Social Worker and the Scissors" in *Better Times*, 151 5th Ave., New York, N. Y., Jan. 5, 1931. 30 cents. Please substitute "public health" for social work in the following:

Books and monographs relating to social work now pour forth in an unceasing stream.

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

But there is one substantial satisfaction about any given book or monograph: generally speaking, there is only one of it!

Not so with the social work periodicals. Finish one issue and lay it aside with a sigh of virtuous satisfaction; the next blast that sweeps from New York brings to your table a new issue, and two other magazines which you had for the moment forgotten.

Allow two successive issues of the same magazine to lie unread and your doom is all but sealed. You lose out on current news. . . . You hear nought of new experiments (called "demonstrations") and new developments in your own field; you smile vaguely and feel inferior when an irritatingly well-read colleague or an omniscient out-of-town speaker alludes airily to that intriguing article in the current issue of *The Social Worker's Companion*. And all the while your stacks of magazines, like the reports described by Walter Lippmann, mount higher and grow mellow and more mellow on your own desk.

. . . There are, however, a few practical suggestions which, if consistently followed, may give the social worker at least a sporting chance of holding his own in the magazine marathon. Here are the suggestions:

1. Put magazine reading into your program. If you haven't a program, read Arnold Bennett's "How to Live on Twenty-Four Hours a Day," and try making one. Magazine reading takes time—just like interviews, "conferences," bridge, and detective stories. . . .

2. Limit your aims. You can't read everything that is written on social work. The most you can hope to do is: (1) to keep up technically and thoroughly with one specialized field of social work—two fields at the most; (2) to maintain an intelligent "current events" or background knowledge of the progress of social work as a whole.

3. Select your magazines with these aims in mind. . . .

4. Develop a technic of reviewing periodicals. Cultivate the art of skimming the unimportant and concentrating on the important. Abbe Dimmet, in *The Art of Thinking*, has charmingly told "how to read the newspaper":

"Others again—few in number—armed with a red pencil and big scissors sit beside a pile of newspapers which they treat unceremoniously indeed. Half the sheets are flung aside while the rest are eagerly but quickly gone over, the red pencil every now and then zigzagging through a column. In less than an hour the seven or eight newspapers have been gone through and the red-marked pages alone strew the table, sofa and piano.

Then the big scissors come into play."

5. Clip your magazines. Generally speaking, the idea of keeping a complete file of a magazine is a delusion and a snare for an individual. . . .

Clipping is infinitely simpler and more satisfactory. Mark the articles which you want to clip, while you are reviewing the magazine. Select for clipping articles which you will probably want to refer to again, because of their permanent value or their importance to your job.

6. Identify your clippings. Write the name of the magazine (abbreviated) and the date of the issue on each clipping. . . .

We are promised an article on filing clippings by Mr. Dunham, but in the meantime would like to hear how some of our readers manage this job.

From the Outside in—Is there a hidden "moral" here for public health workers?

Never before in modern business have merchants become so keenly aware of the fact that the customer is king. Stock is bought, windows trimmed, interiors arranged, salespeople hired and fired, merchandising plans made—all with one eye on the buying public. It is because merchants frankly acknowledge today that they must run their stores from the outside in, rather than from the inside out—that it has become more necessary than ever before to have an accurate and complete close-up view of the buying public.

"Study Your Customers," by Ruth Leigh, *Publishers' Weekly*, Sept. 6, 1930, p. 915.

What Do You Want at Montreal?—Early in January the Council of the Public Health Education Section will meet to plan for the Montreal program and for any possible Section activities before the October convention.

What do you want? Or object to? Or what do you suggest for consideration? Please write to any Section Council member, or to the editor.

The New Mother's Day—A new meaning is to be given Mother's Day, this coming May 10. National pub-

licity emphasizing the high maternity death rate in the United States will precede May 10, according to the Maternity Center Association, 578 Madison Ave., New York, N. Y.

Another Campaign Opportunity— More than 7,000 communities participated in the 1930 Better Homes Week. How sanitation and health will secure recognition in the 1931 campaign is largely up to the health agencies. April 26–May 2 is the 1931 date. Better Homes in America, 1653 Pennsylvania Ave., Washington, D. C., will supply the needed information.

MAGAZINE ARTICLES

Popular articles on disease and health appear in a wide range of periodicals. Professional public health contributions from Dr. Louis I. Dublin and Dr. James A. Tobey have appeared frequently in magazines of general circulation. Doubtless more articles from A. P. H. A. members would be welcomed by editors.

Editors of health department or association bulletins or house organs could do much worse than to quote liberally from many of the published articles listed in this department.

In many cases permission would be given to make quotations to be supplied to factory and office employees' bulletins and other local publications.

"Birth Control and the Moral Law," by Dean Inge. *Atlantic*. Dec., 1930.

"The Common Cold," by Hugh S. Cumming. *Journal*, National Education Assn., Washington, D. C. Nov., 1930.

"For a New Year of Health," by G. F. Alsop. *Woman's Journal*, 171 Madison Ave., New York, N. Y. Jan., 1931. 25 cents.

"Lady Doctor of the Helderbergs," by J. P. Gavit. *Survey Graphic*, 112 East 19th St., New York, N. Y. Dec., 1930. 30 cents. Baby welfare and

medical service in a New York backwoods section.

"Mental Health at Moderate Cost," by Mary Ross. *Survey*. Nov. 15, 1930. 30 cents. Hospital psychiatric service in terms of "Mr. Thompson."

"New Theory of Tooth Decay," quoting Dr. C. F. Bodecker of Columbia University. *Literary Digest*. Jan. 3, 1931.

"Our Menacing Toll of Accidents Attains a New Peak," by Louis I. Dublin. *New York Times*. Dec. 1, 1930. "100,000 deaths our tribute in 1930."

"Science's War for Humanity," by Dr. Francis Carter Wood. *New York Herald-Tribune Magazine*. Dec. 14, 1930.

"When Doctors Disagreed," by J. P. Murphy. *Survey*, 112 East 19th St., New York, N. Y. Dec. 15, 1930. 30 cents. Sympathetic but critical appraisal of the White House Conference.

PUBLIC SPEAKING

Some topics for health talks: "Why Insist on Dying of Cancer?"; "How to Be Happily Born" (prenatal care); "The Sneak and the Mimic" (syphilis); "Patrick, it's bedtime!" ("the unrested child"); "The 'Don't' Mother and the 'Won't' Child" ("insidious parental habits"); "Are You Paid Too Much?" ("economic value of fitness through games and sport"); "Ringworms Round Rosie" ("and other skin troubles in childhood"); "Zulu Beauty Culture" ("has it a place in Canadian civilization?"); "Diphtheria the Outlaw" ("in Germany a death from diphtheria entails legal action against those responsible"); "Growing Pains" ("a stop-look-listen sign: acute pain in or near a joint may be very serious"); "Tremendous Trifles" ("the small, trivial injury"). The above come from the newly organized Greater Vancouver Health League, a branch of Canadian Social Hygiene

Council. From the Winnipeg branch come these titles: "Our Grandmothers as Physicians"; "Therapeutics of the Bible."

NEW

"The Sight-Saving Review," National Society for the Prevention of Blindness, 370 7th Ave., New York, N. Y. First quarterly issue in March.

Designed to meet the needs of state and local prevention of blindness workers, educators, illuminating engineers, school physicians and nurses, safety engineers, public health administrators, industrial physicians and nurses, sight saving class teachers and supervisors, ophthalmologists, and anyone interested in the sociologic phases of saving sight.

The 80 pages will contain original articles, abstracts from current periodicals throughout the world, book reviews, and reports of the Society's activities.

\$3.00 a year. Samples free. The *News Letter on Sight Conservation* will be continued in reduced form and more popular content.

LISTS

Nurses holding executive positions in states, and officers of state public health nursing organizations. *Public Health Nurse*. Jan., 1931.

Whole-Time County Health Officers. *Public Health Reports*. Dec. 19, 1930. Supt. of Documents, Washington, D. C. 5 cents.

VOLUNTEERS

All types of health agencies will be interested in "Volunteer Service for Public Health Nursing Organizations" in *Public Health Nurse*, 370 7th Ave., New York, N. Y. Jan., 1931. 35 cents.

During the fall of 1930, questionnaires were sent by the National Organization for Public Health Nursing to a group of urban public health nursing associations, county health organizations, city health departments, and to school boards, requesting information as to the services which volunteers were rendering. The replies are summarized here, rather in-

formally, and a few general principles deduced from the experiences reported.

In this study, a volunteer job is defined as one that would call for the work, other than nursing, of a paid member of the staff, or the paid work of an outsider, if the volunteer did not do it. The service offered by officers and board members of the organization incident to their positions as administrators is not included.

The replies cover types of service, how recruited, where volunteers come from, training, supervision, advantages and disadvantages. This department is interested because of the potential publicity value of every volunteer. Outside of campaigns few health agencies have discovered the varied publicity services possible through volunteers.

In November a 3-day institute in New York City was attended by 200 board members of nursing organizations from 50 cities in 9 states!

PICTURES WANTED

Our hygiene class is studying the lives of various heroes of health. We are also making a scrapbook in which we would like to put the pictures of these great men. . . .

Could you help us?

The following are the men about whom we are studying:

Jenner	Lister
W. Reed	Wm. Roentgen
Pasteur	Robert Koch
Grenfell	Ser. F. Branting
Theobald Smith	Florence Nightingale
Alexis Carrel	

If you have pictures of others we would appreciate having them.

The New York Academy of Medicine, 2 East 103d St., New York, N. Y., will supply 5 x 7 photographs of the above at \$1.25 each. Photostats \$.25 to \$.50 each.

Are there any better portraits obtainable, and at less cost?

Will an insurance company or some one else provide a *printed* set of portraits for school use?

WHY DO THEY DO IT?

A memorandum of health activities in a city, located east or west of Montauk Point, is headed

A Review of New Activities initiated or accomplished at . . . during the past ten months.

But the memorandum is not dated! Nothing but a real letter is dated—according to the average stenographic mind. The way to avoid trouble in filing and sending out undated material is to have an office rule that *all material* going through a typewriter shall be dated *unless* contrary instructions are issued.

A 4-page T.A.T. folder of special merit is issued by "the Health Department" in some unnamed city. Why the modesty?

REPORTING

"Pursuing Health with one of Henry's Fords" is the cover-page statement, and "or a Day with one of the Dutchess County's Public Health Nurses" is the sub-title across the inside flap of the gaily illustrated folder. It tells all the average person could wish to know about the public health nurse. Paper, typography and layout are way above the average. Dutchess County Health Assn., 16 Cannon St., Poughkeepsie, N. Y. 2 cents.

On the afternoon of December 31, 1930, Health Commissioner Shirley W. Wynne submitted to the Mayor of New York City an 11-page summary report of department activities for 1930. Nearly 200 radio talks were delivered. "More space has been given (in the newspapers) to public health and to the education of the public in health matters than ever before." Of special interest is the war on quacks:

Renewed widespread activities of medical quacks, charlatans and peddlers of questionable nostrums caused the department to take definite action against this menace to health

during 1930. The department made a special appeal to the Federal Radio Commission for assistance in barring these quacks from the use of the air.

As a further aid and safeguard in this campaign, the department, through the assistance of the National Better Business Bureau, has been able to compile what the press has called "The Medical Rogues Gallery," in which upwards of 25,000 names and addresses of quacks, charlatans and manufacturers and peddlers of nostrums have been alphabetically arranged. This is the first time any Department of Health has taken such a step and the directory, it is expected, will form the nucleus of a national gallery in the very near future. When this is completed, any radio broadcasting station can obtain a complete history of any quack who applies for time on the air.

"In Which The Public Health Federation Reports" is the non-report looking cover-title of the 1930 report of the Public Health Federation, 312 West 9th St., Cincinnati, O. Including its brief mention of city, county and state health departments the report offers a cross-section of the diverse health activities of a large city. The newest of the councils within the Federation, the Health Education Council, is explained:

It is made up of physicians, dentists, nurses, health educators and lay people representing public and private health organizations interested in health education, and of general publicity and advertising experts.

The purposes of the council are to coördinate the health education activities of private health agencies, to render such assistance as possible to public health departments, to advise and assist in conducting health education campaigns and programs, to endeavor to prevent overlapping and duplication of health education activities in Cincinnati and Hamilton County.

"Our famous Paul Revere was the first chairman of Boston's Board of Health, and the country's first State Board of Health was established in Massachusetts in 1869."—This the opening paragraph of a leaflet contributed by Massachusetts Dept. of Public Health, Boston, to the Massachusetts Bay Tercentenary. 2 cents.

In *Public Health News*, New Jersey Dept. of Health (Oct.-Nov., 1930), appears "The Year in Review"—tells how "Education Is Often An Indirect Achievement" and that "Education Accomplished by Many Activities."

Transition from policeman to teacher has affected both the work and point of view of health officials. So true is this that nearly every activity of the State Department of Health attempts more or less directly to instruct, interest and lead local officials and citizens to do the right thing for their own well-being and that of their neighbors.

MOTION PICTURES

The Amateur Cinema Club of Toronto, Canada, has been providing amateur movie programs for the patients of Christie Hospital.

American Cancer Society is booking a new picture (both 16 mm. and 35 mm.) of both living normal and cancer cells.

"Clara Cleans Her Teeth," a new film on dental hygiene in 16 mm. narrow gauge stock, is being distributed by New York State Dept. of Health.

Five simple rules for the writing of captions—in "Recipes for Titles," by A. L. Gale. *Movie Makers*, 105 West 40th St., New York, N. Y. Jan., 1931. 25 cents.

Did you see the Red Cross Roll Call "talkie"? A trailer of 150 feet of "action-filled film." Sold at \$15.00. \$7.50 for the silent version.

Exceptional was the procedure of the National Society for the Prevention of Blindness in asking for outside criticism and counsel on a new picture recently. Before the final continuity was decided the picture was assembled and submitted.

To keep in touch with motion picture thought and developments around the world consult *International Review of*

Educational Cinematography, 1-A Via Lazzaro Spallanzani, Rome, Italy. The English edition should be available in large public libraries. For a classified table of contents showing numerous references to health and hygiene send a stamped and addressed envelope to this department.

On the market: a portable sound movie outfit with hand-microphone. You can add the "talkie" to a "silent"; or double with a "talkie." For address write *Movie Makers*, 105 West 40th St., New York, N. Y.

HONORABLE MENTION

To Indiana Tuberculosis Commission: for annual report not looking like an official state report (but the paper did not need to shine).

To Attleboro, Mass., Health Department: for the prominence given to "Health Education and Publicity" in an annual report.

A REQUEST FROM INDIA

Will you send some material? If convenient please tell the editor that you have done so.

For the benefit of health workers and others we are planning to have occasional exhibitions, showing the aims and objects and the type and extent of health education and practical work that is being carried out or has already been accomplished by the big organizations of the world.

May I request the favour of your very kindly helping in the matter by sending this office such literature and other material as you may be able to spare and which may serve the object.

Statistical charts, specimen propaganda literature, in way of booklets, pamphlets, bulletins, posters, pictures, etc., including an annual report, will be highly appreciated.

Hoping to be obliged at an early date.

Signed by Harnath Singh, D.P.H., Publicity Officer, Public Health Department, Punjab, Lahore, India.

BOOKS AND REPORTS

On the State of the Public Health
—*Annual Report of the Chief Medical Officer of the Ministry of Health for the Year 1929*—By Sir George Newman. London: His Majesty's Stationery Office, 1929. Price, 3s., 6d.

It is safe to say that there are no more enlightening documents on public health than those written by Sir George Newman, Chief Medical Officer of the Ministry of Health of England. While they discuss affairs which belong to that country, they are none the less enlightening and useful to those interested in public health in every part of the world.

Some English reviewers point out that the present volume is not as optimistic as usual and confess that 1929 was a bad year, with happenings calculated to give grave anxiety to the health authorities. While we cannot entirely agree with this, the report does point out certain evil tendencies and gives warnings which should be heeded.

It has been evident for some years that both birth and death rates were declining, the proportion of children decreasing, and those past the prime of life increasing, the result being that the average age is steadily rising, making the ratio of deaths to population more unfavorable than formerly. In England the natural increase in population, which was 5 per 1,000 in 1928, was only 2.9 in 1929, indicating one more step toward a stationary population.

The total number of deaths showed an increase of 72,103 over 1928, with a rate of 13.4 per 1,000. Of these, 34.91 per cent occurred under the age of 50; the death rate of infants under 1 year was 74 per 1,000 births. Sixty-four per cent of the total death rate was due to: (i) diseases of the heart

and circulation (225 per 1,000 deaths); (ii) bronchitis, pneumonia, and other respiratory diseases (157); (iii) cancer (107); (iv) diseases of the nervous system (82); (v) all forms of tuberculosis (71). It will be noted that cancer ranked third as a cause of death, the rate being higher than that recorded in any previous year.

Practically every subject which would interest those concerned in public health is treated in order, and the entire report reads more like that of an institute for research than a bare statement of figures such as we usually expect from a board of health. Considerable space is given to education, the author laying stress on the educational value of the development and extension of sanitation, believing that they have a far-reaching effect in developing the "will for health," holding also that, far from decreasing voluntary efforts, it has increased them. Both scientific and popular bodies, as well as such movements as the Boy Scout, the Woman's Institute, Industrial Welfare, etc., show great activity. A note of warning is sounded against "an orgy of public effort or public demand of doing something for everybody," since this may lead to a decrease in the sense of individual responsibility, and the necessity of people doing something for themselves.

This report is commended to all health officers and others interested in public health as a document which stands preëminent. M. P. RAVENEL

Treatment of Epilepsy—By Fritz B. Talbot, M.D. New York: Macmillan, 1930. 308 pp. Price, \$4.00.

The current opinion of a number of school health administrators is that epi-

lepsy is on the increase among school children. Whether this is a real or only apparent increase, it is difficult to decide. It may arise from the change which has been taking place in our conception of epilepsy from that of definite disease entity to a symptom complex, resulting from a number of causes. This is clearly pointed out in Talbot's recent book where he takes up in order all the possible etiological factors and their interrelations. The pathology, diagnosis and cardinal symptoms of each type of the syndrome are concisely stated.

Talbot is perfectly correct in his statement that, "although by far the majority of subjects are adults, epilepsy should be considered a disorder of childhood and youth because it most often begins during the early years of life."

Considerable attention is given to the dietary treatment of epilepsy, which the author feels is of great value. A thorough discussion of the Ketogenic Diet from both a theoretic and practical basis takes up the major part of the volume. An excellent bibliography is provided. The format of the book is up to the usual standard of excellence of the publishers.

R. A. BOLT

The Book of My Life (De Vita Propria Liber)—*By Jerome Cardan. Translated from the Latin by Jean Stoner. New York: Dutton, 1931. 331 pp. Price, \$3.50.*

All who are interested in history owe a debt of gratitude to the translator for this English version of the autobiography of that remarkable man, Girolamo Cardano, known to the English world as Jerome Cardan, who has been described as "sensitive, affectionate, introspective, imaginative, superstitious, humorous, inclined to ideas of self-reproach, with high ambition and hypomaniac industry," and also "the wisest fool and the most foolish wise man of his time." He was skilled in

gambling, music and fishing, but most expert in gambling, having paid his way at Padua by the practice of this art, though he wrote an excellent book advising against it, but giving instruction in it.

He was born at Pavia, September 24, 1501, and died at Rome, September 20, 1576. Fate seems to have been against Cardan. His parents lived apart and his mother tried to destroy him in infancy, while his father maltreated him. It was not until he was 19 years old that he began to receive ordinary instruction in the gymnasium, but in two years he had become so much a master of medicine, mathematics, and philosophy that he was able to discuss these subjects publicly. In his 23d year he went to Padua, was graduated a year later, practised in small towns with some success, and, approximately 10 years later, was called as Professor to Milan. He was 39 years old before he overcame his early handicaps, became prosperous, and lived in some comfort. Later he became perhaps the most famous physician of his time and received many honors at home and abroad.

His has been described as one of the three great autobiographies in literature. It is an interesting document from every standpoint. It has been abused by some, but praised by many of the great men of the 17th and 18th centuries. He is regarded by many as having been the first to show what we now call the scientific spirit, and to have originated the "new order" which was to change the face of the universe."

It is hard to give a fair analysis of his ideas. We must remember his background and the times in which he lived. He believed in astrology and omens, yet was one of the great mathematicians of his time, and responsible for introducing algebra into the schools of Europe. He subjected himself to pitiless analysis

on the one hand, and showed conceit on the other, having recorded a list of 73 illustrious men who gave testimony concerning him. He wrote a number of books on mathematics, astronomy, physics, morals, medicine and divination. He believed in guardian angels, one of whom, he said, attended him for much of his life, though not recognized until the 74th year of his life.

From our standpoint, one of the most interesting chapters is that on his successes in practice, particularly the cure of John Hamilton, Archbishop of St. Andrew's, who for 10 years had suffered from asthma which all physicians had failed to relieve. Cardan prescribed rules for living, among which was the discarding of a feather bed and the use of a linen pillow. The Archbishop improved so rapidly that one cannot help wondering whether he was not hypersensitive to feathers, and if we have not here probably the first case on record of the cure of an allergic disease.

It is impossible to give a fair idea of this book within the limitations of an ordinary review. It must be read to be appreciated. The translator has done an excellent piece of work. Thirty pages of notes explain references and give brief sketches of the many persons mentioned in the text. The printing, illustrations and make-up of the book are all that can be asked.

M. P. RAVENEL

Studies of the Efficiency of Water Purification Processes—IV. Report on a Collective Survey of the Efficiency of a Selected Group of Municipal Water Purification Plants Located Along the Great Lakes. Public Health Bulletin No. 193—By Sanitary Engineer H. W. Streeter. Washington: U. S. Public Health Service, November, 1929. 100 pp.

This bulletin deals with the efficiency of municipal water-purification systems located along the Great Lakes, from

which approximately 10,000,000 people derive their water supply and into which the sewage and industrial waste of about five and one-half million population are discharged. The report is based on a survey of 14 representative municipal water filtration plants situated on the Great Lakes and connecting waterways, including the plants of Detroit and Cleveland. The survey, which was made at the joint request of interested local and State authorities, was an extension of previous surveys of a similar nature made along the Ohio and other rivers of the Middle Western and Eastern States.

Owing to the great importance of the Great Lakes region from standpoints of population, commerce, and industry, the maintenance of safe water supplies along these Lakes constitutes one of the major water-purification problems of the country. With the increasing pollution of sources of water supply located in various marginal zones of the Lakes, this problem is becoming a more difficult one each year, taxing at present, in some instances, the resources of modern water purification.

The difficulties of obtaining safe purified water supplies from the Great Lakes are magnified considerably by the extreme variability existing in conditions of pollution of the lake waters at the several water intakes, which are located in or close to marginal zones of shore pollution, where water movements are subject to the vagaries of winds and countercurrents. In some instances the pollution of these zones probably is subject to seasonal variation, due to large increases in the sewered population residing along the Lakes during the summer vacation season.

A study of the performance of the 14 Great Lakes plants included in the survey revealed some interesting similarities and contrasts in the behavior of these plants, both among themselves and in comparison with purification

systems of the Ohio type. Perhaps the most striking similarity observed was the existence, at practically every plant, of a well defined relationship between the bacterial quality of the raw water, as delivered for treatment, and the corresponding quality of the effluent produced at each successive stage of purification. This same relationship, which is one of fundamental importance, had been noted previously in studies of water purification on the Ohio River and on other rivers.

The most important dissimilarity observed was the marked variability in average bacterial efficiency shown by the several Great Lakes plants among themselves and their disparity in this respect from Ohio River plants of the same general type. Among the Great Lakes plants, divergences in efficiency were indicated as being due in some cases to differences in the average density of raw water pollution and in certain features of plant design and operation. In other instances no reason could be assigned for the inequalities noted.

As regards the comparative bacterial efficiency of the Great Lakes and the Ohio River plants, the former were shown consistently to be slightly less efficient with chlorination included, and decidedly less efficient with chlorination excluded, than the latter group. Detailed analyses of the data failed to disclose the reason for these divergences, which do not appear to be explained as currently assumed, by the relatively lower turbidity of Great Lakes water. It is suggested that they possibly may be due to differences in the chemical composition of the two waters, notably in the hydrogen-ion concentration.

From a study of the relationships observed between the bacterial qualities of the raw waters and effluents of the Great Lakes plants, and from an analysis of their variations, it was concluded, in so far as the production of final ef-

fluents conforming to the revised Treasury Department *B. coli* standard is concerned, that an average density of *B. coli* in Great Lakes raw waters, as delivered for purification, approximating an index of 4,500 per 100 cubic centimeters, appears to represent an upper limit of permissible pollution, beyond which a majority of the Great Lakes filtration plants, as at present designed and operated, would be clearly overburdened. Mean densities ranging from 1,000 to 4,500 per 100 cubic centimeters represent a doubtful zone, within which some plants might be and others might not be overburdened for a significantly large proportion of the time. With average densities ranging below 1,000 per 100 cubic centimeters, the majority of such plants would not be expected to be overburdened except for a comparatively small proportion of the time.

Among the areas studied, the most highly polluted zone of the Great Lakes from which water is taken for purification was located at the extreme southern end of Lake Michigan, where existing purification systems are clearly overburdened. Other zones of relatively high, though not in all cases excessive, pollution were found to be at the extreme western end of Lake Erie, at the outlet of the Detroit River, and along the southern shore of Lake Erie between Cleveland and Sandusky.

H. W. STREETER

Medizin, Gymnastik und Pädagogik im Kampfe gegen die Tuberculose Harmonische Behandlung—By Prof. Dr. Eugen Kisch. Leipzig, Verlag Georg Thieme, 1930. 83 pp., 83 figs. Price, 5.90 Marks; bound, 7.30 Marks.

Dr. Kisch, medical director of the Institute for Bone and Joint Diseases of the city of Berlin and of the Tuberculosis Sanatorium in Hohenlychen, gives the technic and results of heliotherapy

as applied by him in the treatment of tuberculosis of the bones and joints. In the preface Professor A. Bier bewails the fact that the idea is prevalent that it seems to be more important to heal the sick of their diseases than to keep well persons from becoming sick, and cites the experience during the war of the ill effects of prolonged hospitalization upon even the best of the soldiers.

In his sanatorium practice Dr. Kisch uses largely the outdoor life and physical activity favorable for the healthy in his restoration of the tuberculous children to health, but directs, supplements, and extends the exposure of the body at all seasons of the year to the direct action of the sun's rays. It is his contention that it is the heat rays rather than the chemical rays which are most effective. They induce up to a sevenfold increase in local circulatory activity, and the hyperemia continues for several hours after the cessation of the exposure.

Gymnastic exercises, sports and work suited to patients are utilized in connection with exposure of the body. Typical schedules of exposure times and regions of the body are cited and the indications for treatment are discussed. Results of this treatment are tabulated and particular cases illustrated fully by photographs and roentgenographs. These indicate a high degree of success.

C. A. KORFID

Eat and Keep Fit—By *Lyman F. Kebler, M.D., M.S.* Washington, D. C., 1322 Park Road: *Lyman F. Kebler*, 1930. 302 pp. Price, \$3.00.

The author was the late Dr. Wiley's right-hand man for many years and did the medical and chemical work for the postal authorities, the governmental agency which has helped more than any other, and perhaps more than all others put together, in putting fraudulent food manufacturers and advertisers out of business. He therefore has had an

enormous experience in his special line and is well prepared to write on his specialty.

In addition to many standard tables which are found in works on physiology and foods, the book contains a large number of diets and menus, and if followed, the advice given will doubtless serve a good purpose. Fortunately, the craze for the boyish figure shows signs of abatement. Those who really suffer from overweight and wish to reduce can do so without impairing their health by following the recommendations given.

Unfortunately, as we believe, the author recommends some foods which are not entirely free of the charge of being quack remedies. Certainly the advertisements concerning them are open to this charge.

There is an introduction by Dr. Wiley, who opposed food quackery of every sort, and mentioned particularly one of the breads which the author has assisted in advertising and which he mentions in this book. It is a pity that such a good book is marred by this defect.

M. P. RAVENEL

Sterblichkeit und Todesursachen in den Kinderjahren—*Eine Sozialhygienische Untersuchung in den vier grössten Städten Schwedens*—By *Einar Rietz*. Upsala, 1930. In *Acta Paediatrica*. Vol. IX, Suppl. III. 175 pp., 27 figs. in text.

This study is based on the vital statistics of four Swedish cities, Stockholm, Gothenburg, Malmö, and Norrköping, with a combined population in 1927 of 874,733 inhabitants and a total of 23,953 deaths in the ages of 0-15 years between 1913-1927 out of 200,889 births.

The results indicate that the infant mortality of the first month is increased and the distribution of the causes of death in that period is modified by maternal [hereditary would be better]

chemistry and experimental physiology, treating the facts of individual case situations, have produced the real advances in preventive medicine.

Save for Budd's statistical investigation of typhoid fever (*circa* 1859), Ross's investigation of malaria (1899 *circa*), Farr's inquiries into cholera (*circa* 1854), little light has been thrown on the proximate-causal factors of disease by statisticians; at least, medical statistics, dealing with aggregates of human beings, have not initiated in any important respect any steps leading to specific and dependable preventive measures. Nor has it been established to the satisfaction of wholesomely sceptical persons that statistics can serve more than superficially in the movement for connecting preventive work as cause with reduced sickness and mortality as effect.

The present work is divided into three major sections: I. Births; II. Human Constitution, Heredity, Defects and Impairments; III. Sickness and Injuries. Under "births," Dr. Prinzing discusses birth statistics as ordinarily understood, legitimate fecundity and the size of families (distinguished from the concept of "fertility"), sterility, miscarriages and abortions, still-births, multiple births, the sex-ratio at birth, and the puerperal state.

Prinzing apparently conceives vital statistics registration to be primarily a function of the administrative-legal branch of government (as it is and has been in Massachusetts since 1631), rather than that of the administrative-public health branch. Vital statistics may quite properly be regarded as a safeguard for human rights in general and not exclusively as a basis for the enforcement of the right to health, however important that may be.

In the "constitution" group (Title II) we find a full classification of medical anthropometry, and also a good discussion of heredity on the pathological

side. A summary of the statistical methods and sources on blindness, the deaf and dumb, mental defect, cretinism and various crippling disabilities closes this section. The third "title" in the text discusses morbidity statistics in general, the resources in insurance medical statistics, occupational diseases, injuries in general, mental diseases, venereal diseases, alcoholism and long-term disabilities. The second volume of the text will deal with mortality statistics. We may expect this latter book to appear late in 1930. An English translation would be of service to American students of medical statistics.

E. W. KOPF

Recording and Reporting for Child Guidance Clinics—By Mary Augusta Clark. *New York: The Commonwealth Fund, Division of Publications, 1930.*

This masterly presentation of a most difficult subject is the result of painstaking effort expended over a period of years. The details of service bookkeeping described and recommended represent an evolution of procedure and practice in various clinics throughout this country.

As one who has seen much of the work in manuscript and had occasion to put the instructions into practice, the commentator can testify to the usefulness and practicality of the work. While superficially the details may seem overwhelming almost to the point of confusion, in actual practice one finds that the wording is unusually clear and the principles well defined. If the book is used as it was intended, namely as a guide in establishing a basic procedure, it will be found that the forms and numerous outlines lend themselves to more adaptation than is at first apparent. To one interested primarily in so-called clinical procedures and the individual who comes for treatment, recording and

reporting of statistics is likely to seem something of a burden.

The actual labor involved is much simplified when one has such a guide to help in discriminating between what is likely to prove interesting and instructive and what is relatively less essential. Not the least valuable aspect of such a system is that, since the main body of the outline is used by such a large number of the psychiatric clinics throughout the country, there is furnished a basis for comparison which is very helpful in the discussion of problems of mutual interest between various organizations engaged in child guidance.

The book is exceptionally technical and not deemed to be of popular interest, nor for popular consideration.

The use of the term "sibling" as defined on page 68 is still open to serious question. Although that may appear a convenient definition for use on the case data cards, it is likely to lead to confusion if the word is used in the same sense in the body of the social history, where the name of the patient should be entered in its proper sequence among the other siblings. However, that is a minor point and in no way affects the value of the book.

This publication appears particularly timely when the organization of new child guidance clinics in various localities is so much in the air, and it should without doubt head the list of reference works in any library.

HELEN P. LANGNER

Memories and Vagaries—By Axel Munthe. New York: Dutton, 1930. 257 pp. Price, \$3.00.

The tremendous success of *The Story of San Michele* has brought about the republication of this book which first appeared in London in 1898. It has had great success, having gone through 12 printings in one month. It is a collection of unconnected short stories, many of which are in the author's best

style, while others are disappointing when compared with *The Story of San Michele*. There is evidence of the same love for animals, concern over the fortunes of the working classes, pictures of the cholera epidemic in Naples, etc. We recognize many of the same characters.

Had Dr. Munthe devoted his attention entirely to literature, there can be no doubt that he would have made as much of a success in that field as he did in medicine, though there is little question that he owes the background which is so human and appealing to his intimate acquaintance with the lowly, the sick, and the suffering. A delightful book, full of wisdom and kindness.

M. P. RAVENEL

Report of Second Conference on the Health and Wealth of Merchant Seamen—Paris: League of Red Cross Societies, 1929. 326 pp.

The second conference on the Health and Welfare of Merchant Seamen met at Geneva, Switzerland, October 7-9, 1929, under the auspices of the Norwegian Red Cross and of the League of Red Cross Societies. The conference was attended by delegates from fourteen countries, including all of the major powers. Nine international organizations interested in maritime activities were represented at this conference.

The agenda was divided into three general groups: namely, General Welfare in Ports, Medico-Social Organization, and Welfare at Sea. Discussions under this agenda include 43 papers and numerous communications and reports.

All manner of subjects dealing with the health and welfare of seamen are considered in this report. Generally, much of the discussion is devoted to port facilities which afford medical care and decent living conditions for sailors in port, and which shield them from environmental factors detrimental to their health and morale. These include rec-

reational facilities, the operation of hostels and sailors' homes, admission to local hospitals, and the control of prostitution. The control and treatment of venereal diseases is considered at length.

Several papers are devoted to the health and welfare of the sailor at sea. Consideration is given to his medical care on various types of ships. Such minor subjects as ships' libraries and the organization of sports and games aboard ship are also discussed.

In reading this report one cannot help but be impressed with the coördination of activities and the coöperation obtaining between the various organizations which deal with seamen. If work of this kind can be continued in the future, it is certain to be of great benefit to those who sail the high seas.

Necessarily, many of the papers are presented by title only. Nevertheless, the report contains a number of excellent papers and discussions which are well worth reading by those interested in the health and welfare of merchant seamen.

G. C. DUNHAM

Dietetics in Warm Climates—By *J. Neil Leitch, M.D., B.S.* With an Introduction by Brigadier-General Sir *J. A. Byrne.* London: Robinson & Sons, Ltd., 1930.

This is an excellent and comprehensive volume on tropical dietetics, which will be useful to the practitioner in the tropics, the administrator and other residents, or prospective visitors to hot countries.

The wealth of material is divided into 10 chapters, of which the first is the introduction, and the last a discussion of what the future may hold for the health of tropical peoples when the principles of dietetics shall have been applied. The others compose the text, interspersed with voluminous tables of institutional dietaries, as well as tabulations of analyses of food products, etc., derived from government reports, the

publications of research organizations, the statements of tropical workers, as well as the personal experience of the author.

The discussion of the physiology of tropical dietaries, the rôle of salts, vegetables and condiments, the various aspects, composition, effects, etc., of tropical dietaries, both native and institutional, as well as the regimen of the bungalow, are especially interesting and comprehensive.

The lists of tropical foodstuffs, their preparation, preservation, and nutritive values, are welcome and of manifest importance, while the chapters dealing with avitaminosis, and the diseases resulting from defective dietaries, food intoxication, fish, meat, and other forms of poisoning are excellent and concise. The author has succeeded in compressing into a small volume a great amount of essential information well selected and logically arranged.

It is a matter for regret that the author found it necessary to distribute advertisements of foods throughout the book in order to defray in part the expense of publication. These are usually full page, and while not detracting from the value of the contents, are not commendable, and are certainly not customary in works of equivalent worth and importance.

The book is well written, the author introducing what may be called local color, and the printing good.

L. C. SCOTT

A Compend on Bacteriology Including Pathogenic Protozoa—By *Robert L. Pitfield, M.D., and Howard W. Schaffer, M.D.* Philadelphia: Blakiston, 1930. 317 pp. Price, \$2.00.

This well known compend has reached its 5th edition, which in itself proves that it has been useful.

There are a few omissions which detract from its value, as Dorner's stain for spores and Ponder's for diphtheria,

the two best for their respective purposes of which we know. Gram's stain has also been improved by some modifications which are not mentioned, especially that by Hucker.

It is compact, and the descriptions of fundamental principles are clear. It can be recommended as one of the best in its class. The printing and illustrations are good. M. P. RAVENEL

BOOKS RECEIVED

THE GUIDANCE OF MENTAL GROWTH IN INFANT AND CHILD. By Arnold Gesell. New York: Macmillan, 1930. 322 pp. Price, \$2.25.

CLINICAL ALLERGY, PARTICULARLY ASTHMA AND HAY FEVER. By Francis M. Rackemann. New York: Macmillan, 1930. 617 pp. Price, \$10.50.

THERAPEUTIC USES OF INFRA-RED RAYS. By W. Annandale Troup. London: Actinic Press, 1930. 56 pp. Price, \$1.50.

LABORATORY MEDICINE. A Guide for Students and Practitioners. By Daniel Nicholson. Philadelphia: Lea & Febiger, 1930. 433 pp. Price, \$6.00.

HEALTH DEPARTMENT AND OTHER REPORTS

IRA V. HISCOCK

Detroit, Mich.—November issue of *City Health*, the monthly bulletin of the Detroit Department of Health, is largely concerned with the annual report of the school health service for 1929–1930 and brings out the close coöperation between the Department of Health and the Board of Education. An excellent system of physical examinations, combined with a watchfulness on the part of the teachers, results in the discovery of physical defects in need of remedial action. While all parents are urged to have their own physician examine the child before he enters school, if this is not done, the school physicians give the examination during the first year of school. Also, if any child is 15 per cent underweight, he is given a thorough examination, and the teacher trained by a series of lectures and demonstrations, reports “defects or indications of defects of teeth, tonsils, palate, cervical, thyroid, skin, orthopedic system, vision, hearing, and for anemia,” to the school physicians, who then examine and make the report to the parents.

An educational campaign to urge people to have their children given toxin-antitoxin by their own physician is carried on through talks to the parents at the time an older child is examined, and through newspaper publicity. For the past two years, toxin-antitoxin has not been given in the schools, although vaccination against smallpox is continued, some 52,968 children having been vaccinated in the past year. All children of Detroit are referred to their own physician for diphtheria protection. Since discontinuing this work in schools, an intensive campaign has been waged to have preschool children taken to the private physician. All entering children have as part of

their regular history a notation made on their record cards as to their status in regard to diphtheria immunization. If the child has not been immunized, the condition is regarded as a “defect.” Every effort is made to have the parents take care of this defect. Of all kindergarten and first grade children, it was found that approximately 30 per cent had received toxin-antitoxin before entering school.

United States Public Health Service—The annual report of the Surgeon General of the U. S. Public Health Service of the United States for the fiscal year 1930 is an impressive volume describing health conditions and activities throughout the world. Through the International Office of Public Hygiene of Paris, the Pan American Sanitary Bureau, and the health section of the secretariat of the League of Nations, there was provided a constant interchange of sanitary information. A relatively favorable year is reported.

Approximately 350 to 400 cases of psittacosis occurred in the winter with a case fatality of 35 to 40 per cent. Cholera was reported in the Philippine Islands in May. In recent years the plague situation has improved, but during the year the disease appeared in African centers near Mediterranean trade routes. Yellow fever was reported from the West Coast of Africa and also from Brazil and Colombia. Smallpox cases were reported in larger numbers than in preceding years in India, England and Wales, and the United States.

In the United States, influenza reached its peak in January. Decreased birth and death rates are recorded over the previous year. Diphtheria showed a gratifying decline—45 states reported

71.4 cases and 6.6 deaths per 100,000 population. Ten years ago, 37 states reported 137 cases per 100,000 with a death rate of 13. The incidence of meningococcus meningitis increased steadily from 1924 to the winter of 1930, but in the spring the number of cases dropped. Pellagra has been increasing for several years and in 1929 the death rate was 5.5. Forty-five states reported 41,458 cases of smallpox in 1929; and for the period 1927-1929, 114,000 cases with 442 deaths. No instance of the importation from abroad of any quarantinable disease occurred during the fiscal year. At domestic ports, 1,211,796 alien passengers and 988,759 alien seamen were examined by medical officers under the immigration laws.

Demonstration projects in rural sanitation were carried on in 202 counties in 24 states.

While rural health work is applicable to communities in the United States comprising about 60 per cent of our total population, only about 23 per cent of the rural population is so provided. . . . It is the opinion of the Public Health Service and of the state health authorities, as well as of outstanding leaders in the field of public health in our principal educational institutions and elsewhere, that the development of efficient whole-time local health organizations through which all necessary public health activities may be conducted in proper sequence and in proper relation one to the other is the program which will yield a far greater return on the dollar invested in lives saved and sickness prevented among all age groups of both sexes than any program limited to special diseases or to particular elements of the population that has ever been tried out or suggested.

Enlightening accounts are given of investigations of public health problems, of medical services at marine hospitals, of measures for the prevention and control of venereal diseases, and of coöperation with official and unofficial agencies. Attention is called to the opportunities made possible by legislation enacted during the year providing for

the creation of the National Institute of Health, with the Hygienic Laboratory as a nucleus. There is authorized an appropriation of \$750,000 for the construction and equipment of additional buildings. Additional funds have been made available for the expansion in the cancer and industrial hygiene work.

Pasadena, Calif.—One of the most comprehensive health department reports of the year is that of Pasadena for the fiscal period ending June 30, 1930. An Advisory Committee on Public Health was appointed by the local branch of the County Medical Society at the request of the health officer. Following a list of these members are given the names of the department personnel with their positions. An organization chart of community health agencies, and a classified financial statement prepare the reader further for the body of the report, which follows in outline the *Appraisal Form for City Health Work* of the American Public Health Association. The per capita expenditure by the health department was \$.72, while per capita expenditures of other official and voluntary health agencies (including clinics, \$.59, and preventorium, \$.39) amounted to \$1.65.

On the basis of a population of 76,047, a death rate of 12.8 and a birth rate of 14.7 are recorded, while the infant mortality rate was 42.6. There were no deaths from diphtheria, scarlet fever, nor typhoid. Vital statistics tables and effective charts are accompanied by descriptive text.

Early in the spring, acute poliomyelitis appeared in the state, and with the appearance of 2 cases in the city in May, and 25 in June, energies were directed to insure prompt reporting and the collection and early use of convalescent serum. The chief nurse canvassed each case reported during the previous 10 years and attention was

called through the newspapers to the need of serum. Prompt response made possible an ample supply of serum for use locally and in neighboring communities. A 24-hour service was given to physicians by the laboratory and epidemiologist. Cases are charted by weeks, by age, and by months for previous years. "The efficacy of early diagnosis followed by the prompt use of an adequate amount of serum has been apparent throughout this epidemic."

There were 3,076 food handlers examined during the year, in addition to 126 examinations of raw milk handlers and 170 of barbers and beauty parlor operators. Results showed 37 cases of venereal diseases, 5 cases of active tuberculosis, and 4 arrested or suspicious cases of tuberculosis.

The 4 field nurses made 7,844 visits to patients in addition to their infant and preschool conference work, which showed an attendance of 5,349. There were 1,441 vaccinations against smallpox and 1,491 immunizations against diphtheria with which the nurses assisted. A tabulation of laboratory activities, with an appraisal, indicates an unusually effective service scoring 94 per cent. The vital statistics, tubercu-

losis control, and sanitation services also score over 94, while the total appraisal gives the city 721 out of a possible 1,000 points.

Bridgeport, Conn.—The report of the health department for the year ending March 31, 1930, occupies 91 pages of the *Municipal Register*. In 1929, there were 5 diphtheria deaths as compared with 21 in 1928 and 26 in 1927. The drop is credited to more intensive culturing, the use of only fresh and chloroformed Loeffler's blood serum, and toxin-antitoxin administration. Various educational activities of the year included the showing of 27 films with an attendance of 14,485, and 745 lectures with an attendance of 31,177. Lectures were chiefly on oral hygiene and diphtheria control.

The infant mortality rate in 1929 was 70.9, the outstanding causes of death being prematurity and respiratory diseases. A pulmonary tuberculosis death rate of 44.8 is recorded. After a course of instruction on the structure and function of the eye and in testing of vision, the nurses coöperated with teachers in testing the vision of over 4,000 school children.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH. D.

Oral Typhoid Vaccination—Discussing the mechanism of oral vaccination against typhoid fever, the author opens up an interesting field to the student of nutrition.

ARNOLD, L. *Biology of Typhoid Fever and Oral Vaccination.* Illinois Health Quart., 2, 4: 140 (Oct.-Dec.), 1930.

Prenatal Mental Health—Well worthwhile is this discussion of the mental hygiene of the pregnant woman, about which much remains to be said in the promised succeeding issues.

ARRINGTON, W. W. *Mental Health Hints for the Prenatal Period.* Pub. Health Nurse, 22, 12: 610 (Dec.), 1930.

Nursing Opportunities in Child Hygiene—The public health nurse of the future, more an educator and less a "nurse," will be the chief factor in the improvement of maternal and infant hygiene, for which we now have sufficient knowledge and the necessary technics.

BOLT, R. A. *The Relation of the Nurse to Maternal, Infant and Preschool Health.* Pub. Health Nurse, 22, 12: 618 (Dec.), 1930

Milk-borne Disease—Striking indeed is the change in relative position of the enteric diseases and the throat infections in the tabulation of milk-borne outbreaks of disease in New York State during the past 13 years.

BROOKS, P. B. *Milk-borne Outbreaks in New York State.* New York State J. Med., 30, 23: 1418 (Dec. 1), 1930.

Illnesses Among Wage Earners—A statistical analysis of industrial morbidity data based on absences on account of disability among certain em-

ployed groups and persons belonging to sick benefit associations.

BRUNDAGE, D. K. *The Incidence of Illness Among Wage Earning Adults.* J. Indust. Hyg., 12, 9: 338 (Nov.), 1930.

Mental Hygiene Administration—Mental health problems and the objectives of mental hygiene are presented as a challenge to public health administration in a truly stimulating paper. The public health paper-of-the-month which all sanitarians should read and ponder over.

EMERSON, H. *The Mind in the Breaking.* Survey Graphic, 65, 7: 366 (Jan. 1), 1931.

Bottle vs. Breast Feeding—During the first quarter of the first year breast-fed babies gain more than bottle-fed infants; after that time the condition is reversed. Infections were generally lower among the bottle-fed group, giving no evidence of increased resistance caused by maternal milk. The authors urge breast feeding for a limited time, when conditions are satisfactory.

FABER, H. K., and SUTTON, T. L. *A Statistical Comparison of Breast-Fed and Bottle-Fed Babies During the First Year.* Am. J. Dis. Child., 40, 6: 1164 (Dec.), 1930.

Poliomyelitis Statistics—This twenty-odd year statistical study of poliomyelitis in Massachusetts leads to many interesting conclusions. Among others, a striking change in the age grouping since 1918 is shown, the 0-4 age period decreasing markedly with a compensatory increase in the 5-14 year age group.

FORSBECK, F. C., and LUTHER, E. H. *Anterior Poliomyelitis in Massachusetts, 1907 to 1929.* New England J. Med., 203, 23: 1115 (Dec. 4), 1930.

Duration of Breast Feeding—This seems to be the open season for slogans. The virtues of breast feeding are attacked in this paper, which has the rare merit of being most entertaining—a treat to which the reviewer of health literature is seldom exposed.

GARLAND, J., and RICH, M. B. Duration of Breast Feeding: A Comparative Study. *New England J. Med.*, 203, 26: 1279 (Dec. 25), 1930.

Mottled Tooth Enamel—An interesting study of an outbreak of mottled enamel in the teeth of children who used the offending deep-well water supply during the period of tooth development.

KEMPF, G. A., and MCKAY, F. S. Mottled Enamel in a Segregated District. *Pub Health Rep.*, 45, 48: 2923 (Nov. 28), 1930.

Venereal Disease Follow-Up—Social service returned old and delinquent cases, brought contacts and sources of infection for examination, accounted for a third of all new admissions, secured coöperation of outside agencies and generally raised the level of clinic service to the community.

LELAND, H. L., *et al.* Does Follow-Up Social Service Pay in a Venereal Disease Clinic? *New England J. Med.*, 203, 24: 1200 (Dec. 11), 1930.

Industrial and Private Medical Practice—To improve the employee's health habits, to protect him from disease and industrial hazards, to have his defects corrected, to provide preventive early treatment and educational services, and to coördinate industrial, private and state medical services is the work of the industrial physician. How organized medicine can further leadership in these activities is the burden of this paper.

SAPPINGTON, C. O., and MARBAKER, N. D. The Industrial Physician and the General

Practitioner. *J. A. M. A.*, 95, 26: 1955 (Dec. 27), 1930.

Effects of Maternal Nursing—Breast-fed infants grow to be more intelligent, physically superior children, freer from sickness than do those who start life via the bottle route. Animal experimentation and field studies lead the authors to this conclusion, which ought to give comfort to the breast feeding propagandists.

MAURLER and TSAI. Diet and Intelligence. *Illinois Health Quart.*, 2, 4: 131 (Oct.-Dec.), 1930.

Taking the Dust Out of Industry—Workers in dusty trades have excessive respiratory disease rates. Although the general tuberculosis rate has been halved, the rate among workers in dusty trades has increased. Other equally arresting findings are discussed.

RUSSELL, A. E. Dust and Pulmonary Disease. *J. A. M. A.*, 95, 23: 1714 (Dec. 6), 1930.

Atypical Dysentery—A mild dysentery-like epidemic disease causing symptoms that simulate food infections was studied and reported upon. The guess was that it might have been caused by an attenuated Shiga type dysentery bacillus.

SPENCER, R. R. An Unusually Mild Recurring Epidemic Simulating Food Infection. *Pub. Health Rep.*, 45, 47: 2867 (Nov. 21), 1930.

Hypertension in Industrial Workers—Arterial hypertension is an important industrial hygiene problem. Limitation of physical effort depending upon the degree of hypertension is advised.

WYCHGEL, J. N. Arterial Hypertension in Industry. *J. Indust. Hyg.*, 12, 9: 319 (Nov.), 1930.

NEWS FROM THE FIELD

NATHAN STRAUS

NATHAN STRAUS, who died on January 11, was born in Rhenish Bavaria, January 31, 1848. He came to America with his family in 1854, and settled in Talbotton, Ga. In 1866 he entered his father's business of importing pottery and glassware. He was also a member of the firm of Abraham & Straus, whose department store is located in Brooklyn; but he retired to devote his time to philanthropic work in 1914. He was president of the New York City Board of Health during 1898.

In 1892, a tragedy in his own family was responsible for the organization of the Straus milk stations, where pasteurized milk was sold to the poor at or below cost. His 2-year old daughter died on a trip to Europe, and it was thought that her death was due to contaminated milk. He began to make a study of methods for keeping milk and distributing it in better condition in order to save the lives of other children. It is said, "He helped three babies to live where only one had survived before."

At different times he has maintained centers for the distribution of milk, coal, food, and ice to the poor in New York City. In 1916 he sold his yacht and gave the proceeds to feed war orphans. In 1918 he started the distribution of pasteurized milk to soldiers and sailors, and in 1920 turned over to the Health Department of New York City his pasteurization laboratory and its equipment to be used for preparing ready-to-drink modified milk in nursing bottles. He was responsible for the first preventorium in the United States in 1909, in the Grover Cleveland cottage in Lakewood, N. J., and when residents of the

neighborhood objected, Arthur Brisbane gave 170 acres in Farmingdale, N. J., as a new site, and Nathan Straus gave \$50,000 toward the building fund.

In 1904 he first went to Palestine, and shortly thereafter began his work there for, first the sick, old, and blind Jews who had returned to spend their last days there, and then extended his relief work to include those of all races and creeds.

Mr. Straus celebrated his 80th birthday by sending funds to relieve the unemployed in Palestine, and also erected two health and welfare centers for all peoples, one in Jerusalem.

He was presented with the city flag at the Silver Jubilee of Greater New York in 1923 for services rendered during the preceding 25 years.

In 1895, during his early interest, pasteurization was still under suspicion, and politics entered the battle against it. He was indicted by a grand jury on a charge of watering milk. The fact was that his milk stations had diluted milk in accordance with a medical formula, to be fed to infants. It pleased Mr. Straus greatly later to recall this incident when the world was following in his footsteps in health work.

He was the author of many pamphlets on pasteurization. In 1917 his wife, Lina Gutherz Straus, published the book *Disease in Milk—the Remedy Pasteurization. The Life Work of Nathan Straus*, which included articles, reports, and letters by many well known physicians and others on the subjects of pasteurization and preventoriums. Mr. Straus has been a member of the A. P. H. A. since 1903.

SHORT SCHOOL FOR SEWAGE WORKS OPERATORS

A SHORT school for Sewage Works Operators, sponsored by the New York State Conference of Mayors, New York State Sewage Works Association, and the New York State Department of Health, was held at Union College, Schenectady, N. Y., January 26-31, 1931.

The purpose of this short school was to offer intensive training in the fundamentals of sewage disposal and in sewage plant operation by means of lectures, demonstrations, individual laboratory work and discussion.

ANNUAL MEETING OF THE AMERICAN SOCIAL HYGIENE ASSOCIATION

THE annual meeting of the American Social Hygiene Association was held at Hotel Pennsylvania, New York, N. Y., on January 23 and 24.

The subject for the afternoon session on the 23d was "Social Hygiene Educational Campaigns in Chicago and New York." A dinner was held at 7 P.M. and the following speakers took part in the program: C.-E. A. Winslow, Thomas Parran, Jr., Valeria H. Parker, Edward T. Devine, Jay F. Schamberg and Max J. Exner. The annual business meeting was held on the 24th.

SCHOLARSHIPS IN HEALTH EDUCATION

TWO full tuition scholarships of \$500 each are available for women in the field of health education at Massachusetts Institute of Technology (Department of Biology and Public Health) for 1931-1932. These scholarships cover the full scholastic year, beginning in September and closing in June.

The scholarships will be awarded on June 26, 1931, and applications should be sent not later than June 1 to the Child Health Education Service of the National Tuberculosis Association, 370

Seventh Avenue, New York, N. Y., for application blanks.

ANNUAL MEETING OF THE JERSEY CITY HEALTH COUNCIL

AT the Annual Meeting of the Jersey City Health Council held January 9, Bernard S. Coleman, Executive Secretary of the Hudson County Tuberculosis League, was reelected President for 1931. Other officers elected were as follows: Dr. Howard S. Forman, Honorary President; Ira M. Gast, Ph.D., Vice President; Adele McLoon, Treasurer; and Margaret Shea, Secretary.

NEW VENTURE IN MENTAL HYGIENE EDUCATION

THE Massachusetts Society for Mental Hygiene announces that through the generosity of the Godfrey M. Hyams Trust it will begin the publication early in January of a quarterly, *Understanding the Child*. This new magazine will be distributed free to every teacher in the public schools of Massachusetts. Its purpose is to bring to them a knowledge of the principles and practices of mental hygiene.

The Editorial Board for this new magazine will consist of J. Mace Address, Editor, and Dr. E. Stanley Abbot and Dr. Henry B. Elkind, Associate Editors. There will be a Consulting Editorial Board of fifteen members, composed of experts in the fields of mental hygiene and education.

A small annual subscription fee to the magazine will be charged for those who are not public school teachers in Massachusetts.

WORK FOR THE BLIND

DAVID Resnick has been appointed Director of Publicity for the World Conference on Work for the Blind, which is to be held in New York City

in April, 1931. President Hoover has invited fifty-two nations to participate in this conference.

DR. PETER TO ORGANIZE HEALTH EDUCATION FOR CHINESE GOVERNMENT

AT the invitation of the Chinese Ministry of Health, William W. Peter, M.D., F.A.P.H.A., Director of the Health Service of Cleanliness Institute, New York, N. Y., will go to China some time in February to help organize a national health education program for the Nationalist Government.

The directors of the Association of American Soap and Glycerine Producers, which supports Cleanliness Institute, have granted Dr. Peter 8 months' leave of absence with salary to enable him to undertake this special mission.

ALABAMA DAIRY MARKET SURVEY

L. C. BULMER, Director, Bureau of Food and Dairy Inspection, Jefferson County (Ala.) Board of Health, is directing, in behalf of the Alabama Industrial Development Board, a state-wide survey of Alabama Dairy Markets. The twelve largest centers of population are to be embraced in the survey.

BAUSCH MEMORIAL BRIDGE DEDICATION

ON New Year's day, the city of Rochester dedicated its newest and finest span across the Genessee River as the Bausch Memorial Bridge in honor of John Jacob Bausch, the founder of the Bausch & Lomb Optical Com-

pany. Mr. Bausch was a pioneer manufacturer of optical apparatus and has helped bacteriologists in this country greatly by his interest in science.

IOWA COUNTY HEALTH WORK

THE State of Iowa is moving forward in the development of its county health work, as evidenced by a recent report which states that Dr. E. R. Coffee of the U. S. Public Health Service has been detailed to the state in connection with county health work for a 2-year period. Full-time health units have already been established in Washington, Woodbury, Des Moines and Plymouth Counties. Two other counties, Johnson and Scott, are ready to organize.

THE PUBLIC HEALTH NURSE

THE *Public Health Nurse* announces a special number on Industrial Nursing, February, 1931.

DR. ADOLF MEYER RECEIVES FIRST AWARD OF THOMAS W. SALMON MEMORIAL

DR. ADOLF MEYER, Professor of Psychiatry of Johns Hopkins University, will receive the first award under the recently established Thomas W. Salmon Memorial. Dr. Meyer was selected in recognition of his distinguished services to psychiatry and mental hygiene over a period of years. The award carries with it an honorarium of \$2,500, and the recipient will give The Thomas W. Salmon Lectures during 1931.

PERSONALS

DR. PAUL M. LOWELL, Senior Medical Officer, Food and Drug Administration, U. S. Department of Agriculture, passed away at the Walter Reed Hospital on January 3, 1931.

JAMES CLARKE BRIGGS, of Selma, N. C., who gave his age as 108 years and believed himself to be the oldest physician in the United States, died on January 23, 1931.

DR. ARTHUR D. LITTLE of Cambridge, Mass., a former president of the American Chemical Society, was the recipient of the Perkin Medal, which is awarded annually to the American chemist who has most distinguished himself by his services to applied chemistry.

DR. HUNTINGTON WILLIAMS has been appointed secretary of the State Department of Health, Albany, N. Y., to succeed Dr. Edward H. Marsh. He will also serve as secretary of the Public Health Council.

DR. FRANK E. COUGHLIN has been provisionally appointed epidemiologist in the Division of Communicable Diseases, New York State Department of Health, Albany, N. Y.

DR. JOHN M. T. FINNEY of Johns Hopkins University, Baltimore, Md., and Dr. David Riesman of the University of Pennsylvania, Philadelphia, Pa., will join Dr. Roger I. Lee, consultant in internal medicine, of Brookline, Mass., as consultants of the Committee on the Cost of Medical Care.

E. G. EGGERT, for the past twelve years assistant sanitary engineer of the Texas State Department of Health, has announced his resignation from that office for the purpose of entering private practice, with headquarters in Austin.

DR. OSCAR DOWLING, recent State Health Officer of Louisiana, was killed in a railroad accident on January 2. He was a Charter Fellow of the A. P. H. A.

CONFERENCES

Feb. 16-18, Council of Medical Education and Hospitals of American Medical Association, Chicago, Ill.

Feb. 18, American Conference on Hospital Service, Chicago, Ill.

Feb. 19-21, White House Conference on Child Health and Protection, Washington, D. C.

Mar. 23-27, College of Physicians, Baltimore, Md.

Apr. 2-4, Association of Anatomists, Chicago, Ill.

Apr. 12-15, Tenth Annual Convention, International Society for Crippled Children, Cleveland, O.

Apr. 13-16, American Red Cross, National Convention, Washington, D. C.

Apr. 14-20, World Conference on Work

for the Blind, New York, N. Y.

Apr. 29-30, Conference of State and Provincial Health Authorities of North America, Washington, D. C.

May 5-6, National Conference on College Hygiene, University of Syracuse, Syracuse, N. Y.

May 11-14, National Tuberculosis Association, Syracuse, N. Y.

June 1-5, Psychiatric Association, Toronto, Can.

June 1-4, American Federation of Organizations for the Hard of Hearing, Inc., Chicago, Ill.

June 8-12, The American Medical Association, Philadelphia, Pa.

The Amelioration of Atmospheric Pollution*

HOWARD WHIPPLE GREEN, F. A. P. H. A.

Sanitary Engineer, Cleveland Health Council, Cleveland, O.

MOST large industrial cities are faced with the problem of the amelioration of atmospheric pollution. The magnitude of this problem may be illustrated by the results of measurements conducted in Cleveland during a 24-month period, June, 1927, to May, 1929. During this period, an average of 119 tons of material per square mile per month was deposited from the atmosphere at the collection station located in the downtown district. This, when analyzed, showed 23 per cent carbon and 77 per cent ash, of which 30 per cent was Fe_2O_3 . Nearly one-fourth, 24 per cent, of the total deposit was Fe_2O_3 . In addition to the material which could be collected, large amounts of carbon monoxide and dioxide, ammonia, chlorine, nitrous and nitric acid, sulphur dioxide, trioxide, sulphurous (SO_3) and sulphuric acid, and hydrogen sulphide remained in the atmosphere to corrode the buildings, play havoc with ornamental iron and metal work, and pass through the lungs of the residents. Although the atmosphere in Cleveland is not nearly so polluted as that in many cities in the United States, some days when one drives into the city from suburbs, college days are brought back as all the familiar odors of the college chemical laboratories enter the nostrils.

The solid and gaseous pollution in the atmosphere emanates from many sources. Not all of the solid pollution originates in the combustion of coal; dust and dirt particles blown into the air make up some portion; iron from the working of this metal, from industrial

* Read at a Joint Session of the Public Health Engineering and Industrial Hygiene Section of the American Public Health Association at the Fifty-ninth Annual Meeting at Fort Worth, Tex., October 30, 1930.

grinding processes, and from the wearing of street car rails and brake shoes; products resulting from the wear of asphalt pavements; minute particles of rubber from the wearing of tires and even rubber heels, are present in the atmosphere as well as the products of many other sorts of wear. Organic matter such as wood fiber, lint, and even grasses is also found in the deposit.

Unpaved streets, bare areas between street and sidewalk, playgrounds, back yards, parking lots, and other areas unprotected by vegetable growth provide prolific sources of atmospheric dust. The handling and storage of crushed stone, gravel, sand, lime, cement, brick, and tile increase dust production. Wrecking old structures and building new ones, constructing new streets and repairing old ones, transportation of merchandise, coal, ashes, brick and sand over city streets result in scattering materials on the street. The amount of this dust in the atmosphere depends upon the efficiency of city sanitation and standards of municipal cleanliness, as well as upon the methods employed in street cleaning.

A comparison of the deposit collected in the industrial area with that in the residential areas is of interest:

Region	Tons of Fe_2O_3 per sq. mile per month
Industrial	28
	17
	14
Residential	6
	5
	4

An appreciably greater amount of Fe_2O_3 is deposited from the atmosphere in the industrial regions. It may be assumed that little or no Fe_2O_3 originates from the combustion of coal.

It is already evident that the prevention of the black smoke which is so evident when being belched forth from the chimney is only part of the problem, but it is the only part which has as yet received serious consideration by municipal codes regulating air pollution.

The production of carbon monoxide and carbon dioxide by automobiles is receiving some attention, especially in tunnels used by motors and in the congested traffic in the valleys of our large cities.

The amelioration of air pollution may be analyzed by type of production. The type of fuel, the type of combustion chamber, the size and height of chimney, and the method of firing, all affect the problem of smoke production. Low volatile coal produces little smoke, while anthracite and coke practically none, even though other factors are

most unfavorable. The deposits of this coal are limited geographically; they are expensive; and higher volatile coals are more commonly used.

The size of the combustion space is most important and must be large when high volatile coal is to be burned without producing large amounts of black smoke, and must be calculated for each grade of fuel used. A high volatile soft coal requires a larger combustion area than a low volatile soft coal, while anthracite may be used satisfactorily with less combustion space and coke with still less.

The draft depends upon the height of the chimney, and the volume of air provided for combustion upon the size or cross-section area as well. The necessary height and size of the chimney may be calculated with a high degree of accuracy when the type of fuel and area of combustion surface are known.

The draft may be increased by the installation of blowers or steam jets, provided the area of the chimney is sufficient to carry away the gases afterward.

Mechanical stokers aid in the solution of the smoke problem. The over-feed type with low volatile fuels reduces the smoke because the feed is uniform and not dependent upon an erratic fireman.

An under-feed mechanical stoker feeds high volatile coal uniformly from beneath, which allows a gradual distillation of the volatile matter allowing for complete combustion and little smoke.

Powdered coal, if so fine that it will burn completely in suspension when blown into the fire box by a stream of air, is partially satisfactory, in that no black smoke is emitted from the stack in a proper installation, but probably 80 to 90 per cent of the ash is carried out of the stack, a much greater percentage than when other methods of firing are utilized. Devices have been designed to collect this ash but they are all expensive. The electrical precipitation method, designed originally by Cottrell for the precipitation of suspended metals in reduction plants operated in connection with mining projects, is one of the most satisfactory. This equipment is fortunately being installed by the larger plants using powdered coal, but unfortunately is too expensive for the medium size and small plant.

Smoke production by railroad locomotives may be reduced to a minimum by the installation of fire brick arches in the fire box, automatic stokers of the spray type, and by introducing forced draft in the fire box. Good steam jets should be installed and used when the locomotive is standing in the station or yard. When running, the exhaust from the cylinders passing through a blower nozzle creates a vacuum and draws a larger quantity of air through the combustion chamber,

reducing the amount of smoke which would otherwise be produced. Electric locomotives, as at present operated in Cleveland, of course eliminate the problem completely. The possibility of using gas-electric or oil-electric locomotives in the meantime might be seriously considered.

The stacks serving oil burners give forth no black smoke if operated properly, although the worst possible production of carbon may result if the air mixture is not properly handled. The innocent looking stack, however, emits large quantities of sulphur acids, which are disagreeable to the sense of smell. The sulphur acid fumes corrode steel, rot draperies and clothing, and cause other little suspected damages.

The production of sulphur acids is equally as serious when coal is burned. Under the very best conditions the soft coal in Cleveland carries 1 per cent of sulphur, which means 20 pounds of sulphur per ton, 75 per cent of which may be calculated as to be emitted from the stack. If all the sulphur were oxidized, 175,000 tons of sulphuric acid (H_2SO_4) would be emitted from the stacks in Cleveland during the year. No practical method has yet been devised for taking care of this evil.

The pollution introduced in the atmosphere by industrial plants is a problem in itself; in fact, a more complex problem for the large industrial city. Furnaces for metallurgical, manufacturing, and allied processes pollute the atmosphere with finely divided particles of various metals which appear as waste in manufacturing processes.

Replacing electric furnaces for the cupola with blast twyer which involves air blasts carrying large quantities of fine dust of steel and iron into the atmosphere improves the situation even though the circulation caused by the intense heat of the electric furnace carries some ash into the atmosphere.

Smelting furnaces for melting metal for castings may be handled by installing hoods over the open furnaces and providing settling chambers or bag dust collectors.

The blast furnace properly designed and operated does not present a great problem as the gases are now collected, cleaned and used to drive engines for power.

The operation of by-product coke plants pollutes the atmosphere, especially when being charged. In Cleveland the period of charging has been reduced from 9 to 4 minutes through careful time studies made by the City Department of Smoke Inspection. Further reduction of pollution is effected if the installation is designed as a wet seal process, which involves the gas pipes dipping into the tar mains.

The more extensive use of household incinerators, as well as the larger municipal types, introduces additional problems. When 60 per cent of the material to be incinerated contains 90 per cent water, it is unreasonable to expect the remaining 40 per cent to produce enough heat to evaporate this large amount of water and maintain temperatures high enough to insure complete combustion of the entire mass. In the large installations auxiliary oil or gas burners are usually necessary to raise the temperature of the gases sufficiently to guarantee complete combustion.

Some amelioration may be expected due to the careful inspection and intelligent advice of the smoke inspector relative to types of fuel, methods of feeding, and alterations in the equipment. The most optimistic feature of this whole problem lies in the fact that in most cases the necessary improvements result in sufficient savings in the fuel bill and labor expense to pay the cost within a short time, in some cases even within a year or a year and a half. Supervision by competent technical men of design and installation, and operation of all plant equipment burning fuel will in time reduce the preventable air pollution to a minimum.

The fundamental work of smoke control is in the prevention of the installation of improper equipment, improper types of stokers for the fuel to be used, undersized combustion chambers and stacks which will not produce sufficient draft for proper combustion.

Tuberculosis in the Philippines

THE Philippine Legislature has just passed a bill which has been signed by Governor-General Davis providing for the creation of a Tuberculosis Commission and appropriation of 200,000 pesos (\$100,000) for carrying out the objects for which the Commission was formed.

The passage and approval of this measure has been largely due to Colonel M. A. DeLaney, Medical Corps of the United States Army, Chief Medical Adviser of the Governor-General.

According to his report, tuberculosis leads all other diseases as the cause of illness and death in the Islands, and while it is decreasing elsewhere in almost every part of the world, it shows a constant increase in the Philippines—from 13,338 deaths in 1904 to 32,814 in 1929. Among the 13 million inhabitants, it is estimated that there are constantly present 500,000 cases of tuberculosis, and this is regarded by many as conservative. It causes 12 per cent of all deaths and even in the City of Manila, there were 1,949 deaths in 1929, against 1,737 for 1928. The chief causes seem to be lack of education, insufficient food, poor housing conditions and lack of isolation of open cases. There are only 300 beds available for the disease in the entire Islands.

The committee looks forward to the establishment of sanatoriums and widespread education in hygiene.

Hazards of Commercial Health Advertisements^{*}

IAGO GALDSTON, M. D., F. A. P. H. A.

Executive Secretary, Medical Information Bureau, New York Academy of Medicine, New York, N. Y.

SOMEWHERE in the writings of the Ancient Hebrews there is the tale of one of their kings who on the eve of an important battle consulted the oracle for advance news on the battle's result. The priest to whom the Hebrew king addressed his inquiry went through the elaborate ceremony of the ritual, and then announced in a deep, stentorian voice that the oracle revealed that a great kingdom would be lost on the morrow. "Yes," said the king, "that's all very good, but ask the oracle, whose kingdom will be lost on the morrow, mine or mine enemy's."

"O most mighty king," replied the priest, "on that score the Oracle is dumb."

The provocation of this story lies in the title of this paper assigned to me by the makers of the program—"Hazards of Commercial Health Advertisements." But, hazards to whom?—to the advertisers? to the public? to the advertising agencies? or to the health education movement? A great kingdom is to be lost—but whose kingdom? And yet it is well that the discussion was not prejudiced in advance by greater definition in the title. For, in truth, perhaps the hazards do confront all agencies mentioned, and others besides.

We are agreed only that there are hazards in commercial health advertising. We are left free to discuss their nature and the scope and embrace of their threat.

Pressed for a statement of the greatest hazard involved, I should say it is this—that the public health movement, and particularly its health education section, go on as it has so largely done in the past, ignoring commercial health advertising, opposing it, as the temptation to do so is great, and dealing with it as an interloper and upstart disrespectfully intruding into our sacred precincts.

In this attitude, I should say, resides the greatest hazard. But I must hasten to add that this very conference, our very willingness to

^{*} Read before the Public Health Education Section of the American Public Health Association at the Fifty-ninth Annual Meeting at Fort Worth, October 30, 1930.

consider this problem, is an indication of our awareness of that danger, and of our eagerness to escape that threat.

It is imperative that we should realize that commercial health advertising is a permanent phase of our social existence. Truth to tell, it has been with us for more than a score of years, if we take the Metropolitan Life Insurance Company's welfare activities as an instance of commercial health advertising. We have recently become more acutely aware of its existence because of the phenomenal development of the health appeal in commercial advertising during the post-war years.

Furthermore, we must realize that commercial health advertisements are essentially legitimate, that no matter how this practice may be abused, the producer of a commodity cannot be disbarred by any abstract rule of justice or of ethics from persuading the public, through the promise of health benefits, to purchase his products.

In a word, commercial health advertising is here with us; it is here to stay; it is bound to develop and extend further; and, we must admit, it is a legitimate phase of business and social life.

In the light of these facts, what are we to do, we who are interested in safeguarding the health of the public, we who are particularly interested in health education?

In this connection, I am reminded of Elbert Hubbard's homely but wise stricture to the effect that the wise man is he who takes the lemons that fate hands him and goes into the lemonade business. Commercial health advertisements are not lemons in the sense in which the word was employed by Elbert Hubbard, but we should and must go into business with them. We must, to employ another phrase, play ball with the commercial organization whose promotional activities lead them into the field of health education.

That this can be done, and effectively too, is demonstrated by our experiences with the Metropolitan Life Insurance Company, with Squibb & Sons, Endicott-Johnson and a few other commercial organizations. An equally convincing demonstration of this fact can be seen in the commercial exhibits connected with this Annual Meeting, and in the commercial advertisements which fill the advertising pages of many thoroughly ethical medical and health magazines.

The deeper they reach into the everyday life of the people, the more effective are public health work and public health education. Commerce is a large part of the everyday life of people, and advertising is a large part of commerce. *Nolens volens*, we must face these conditions, and master them to the benefit of the public, of business, and of ourselves.

Commercial organizations have recognized these facts. They have in many ways sought to do business with us. They are receptive, in a larger measure than many among us appreciate, to our suggestions and advice, and they have a wholesome respect for the force of our opposition.

In all these respects our position would be strengthened by a well defined stand on commercial health advertising. At present, with but one or two exceptions, there is no such well defined stand taken by representative bodies. In New York City our Academy of Medicine, in coöperation with the County Medical Society, has created the Medical Information Bureau, to which advertisers, advertising agencies, and newspapers can turn for advice on health matters.

Scores of these commercial agencies have made use of this service. Many of them have offered to pay for what they received. Most of them have done business with us on a strictly ethical and legitimate basis. They have shown themselves willing to sacrifice appealing copy in order to gain veracity, and a certain portion of promised immediate gain, for good will.

The American Medical Association has recently established a comparable service. It now certifies certain foods and other products which meet its standards on composition and advertising. It issues a shield which producers and advertisers may use on their labels and in their advertising copy. This service promises to be of benefit to the public and to business. It constitutes a step in the right direction.

Desirable as I judge these developments to be, I am not unaware of the hazards involved, and having dedicated the first part of my paper to a plea for closer coöperation with commercial organizations whose business brings them into the health field, I shall now discuss the dangers involved.

These differ, as the commercial organizations differ, and, while we employ the term commercial health advertising to indicate a certain type of activity in the health field, there are a number of subdivisions and classifications possible under this heading, and an appreciation of these is desirable for a better understanding of the hazards involved.

We may classify commercial organizations conducting, or liable to conduct, health advertisements, under 4 general heads. There are, first, those organizations whose primary interest it is to keep people well and alive. Conceivably, this ought to be the interest of all business organization, with the exception perhaps of morticians, tombstone makers, and the like. Factually, however, only the life insurance companies figure prominently under this heading; their prominence, however, is great. Probably without exception, the insurance

companies spend more money on health education, health advertising, than any other commercial group. They alone of the sellers of commodities, due to the nature of their business, have an entrée into the homes of people as free and intimate as that of the district nurse or the tuberculosis worker. In the main, and with no exceptions known to me, the health advertising of life insurance companies has been acceptable, both to the critical scientist—jealous of the accuracy of the facts—and to the public health administrator—who is concerned with the trend and development of public health progress.

The past performance of these commercial organizations in the field of health education has been gratifying. It is also reassuring as to the future. One could conjure up for the easily horrified a disconcerting picture of what tremendous damage the life insurance companies, with their vast financial resources, their thousands upon thousands of agents, their closely integrated network of offices that cover the continent, might do by going off on a tangent. But such a picture would be more in the nature of a nightmare than a possible, or probable, forecast of the future. At the worst, we in the public health field might find ourselves, in relation to the life insurance companies, like the man who was loved by a bear, and who was affectionately hugged, but at the same time was pressed a little too hard for comfort. The insurance companies might at times press us too hard in certain directions of health work.

There is no great hazard in this group of commercial health advertisers, nor is the hazard liable to increase with the appearance of other and additional types of insurance organizations covering sickness, accident and old age.

The picture becomes a little more complicated as we face the second group of commercial health advertisers, in which we place all the producers and vendors of staples, such as foods, beverages, household goods, and clothing. Unlike the life insurance group, these commercial organizations are not directly interested in the promotion of health and the prevention of premature death. They, on the contrary, are interested in selling their commodities. They employ the health motive as a sales appeal, and as a promotional argument. "Buy this because it is good for you," is largely the essence of their advertising. "Use my product, and more of it, because it will help to improve or safeguard your health," is the substance of their messages.

Here again let me say that, in my opinion, the use of health as an advertising motif is in essence legitimate. More than that, it has been useful, having motivated producers of various commodities, from shoes to bed springs, to produce not only profitable but also hygienic prod-

ucts. Though this is not the happiest illustration possible, I call, in witness of this last point, the expeditiousness with which cereal producers applied irradiation to their breakfast foods, and used the alleged antirachitic value of this process as a sales argument.

However, precisely in this very case may be seen one of the hazards of the health advertising conducted by this second group of commercial organizations. They are liable and prone, by a salesman's zeal, to overemphasize, over-stress, and so distort health facts that from being facts they become fallacies.

Take, as an instance, the commodity milk. Who can deny that splendid work has been done by the dairy group in extending the consumption of this most useful food? And yet, in recent months there have appeared a number of scientific contributions from pediatricians complaining that milk has been oversold, that the standard formula of so many glasses of milk for every child every day is fallacious; that it does not take into account the possibility of a child's partial or complete intolerance to milk; nor does the dairy propaganda recognize that in certain children suffering from anorexia, the standard milk diet is highly undesirable.

In the opinion of many physicians, some communicated to me personally and others culled from current literature, fruits and vegetables too have been "oversold" to a portion of the public. Gastroenterologists meet with an ever increasing number of intestinal disturbances, and particularly with hypermotile colons, due to a fruit and vegetable diet which leaves too large and too irritating a residue of cellulose.

Whole grain versus milled flour bread is another item to be cited in illustration of our contention, with the brown claiming all the virtues of health giving, white bread on the defensive, and the public in a state of partisan intrenchment or bewilderment.

It is not pertinent to the argument that there are many communities where individuals do not drink enough milk, nor consume a minimally safe quantity of milk products; neither is the point that many do not consume enough fruit or vegetables. These facts, as such, are granted. So also, however, must be granted the fact that in the health advertising of many commercial organizations dealing in staples there is the ever present hazard of the distortion of facts, of overemphasis, of isolation and elevation of the value of one commodity or practice over others equally worthy of attention.

This last fault is particularly patent where certain of these commercial organizations enter with their materials into our schools. They give to the teacher complete health lessons, and attractive ma-

terial on, say, cleanliness, or milk—and what is the result? Their particular item is so stressed that the child too frequently is left with a distorted notion of the value of a daily bath, or of washing his hands, or of brushing his teeth, or of drinking milk.

I appreciate well that there is much that can be said in extenuation by the commercial organizations mentioned or implied in my argument, and it is far from my intention to lay the whole blame for these conditions at their doors. I construe my task as being merely to cite the hazards, and not to assign, or to apportion their source.

With the third and fourth groups, we need not at this time concern ourselves for long. In the third, I place all those whose products are cosmetic or “comforting” in character. They are large in number, as may be seen in glancing through the advertising pages of any so-called woman’s magazine. They include many soaps claiming special virtue as germicides, extreme purity, medicinal qualities and the like. Dentifrices, too, fall in this class, especially those which “harden the gums,” “prevent pyorrhea,” “protect the danger line,” “destroy decay producing bacteria,” and “whiten the ivory.” Feminine hygiene products, deodorants, skin foods, hair tonics, toilet papers, shaping garments, wrinkle removers—all these and others, too numerous to mention, belong in this group. They represent a hazard of waste. They mulct the public to the sum of hundreds of thousands of dollars. They distort the common person’s viewpoint on health, physiology and hygiene. They encourage practices which are sometimes injurious. They create a false sense of danger, as in the case of an advertisement which boldly stated that some 14 different painful and distressing diseases might arise from the use of unsuitable toilet paper.

The fourth group includes the vast sphere of the nostrum and the quack, a sphere too well known to you to need elaboration. With their health advertising, we are all acquainted; so too are we cognizant of the hazards involved therein.

I mention this last group, and also the third, for a particular reason. It is to point out that as we are obliged to coöperate with the first mentioned two groups, so are we in duty bound to combat the fourth and in part the third. Furthermore, to the extent that we support the health advertising of the legitimate commercial organization, to that extent will we be supported in our fight against the nostrum and the quack.

Legitimate business is interested in better business and in better business methods. Wildcat tactics are out of style. Even though in recent years there has been a sudden flaring up of objectionable advertisements, with a large ingredient of pseudo-health appeal, we must

not be misled by their appearance into believing that we have retrogressed, rather than progressed in the direction of more honest and more constructive advertising.

Legitimate business is hurt by the quack and the charlatan. We could, I believe, wage a more effective war on these parasites if we had the good will of the honest commercial health advertisers. This good will we can gain through coöperation.

A recent advertisement in the New York papers illustrates the subtle way in which commercial advertisers can coöperate with health workers. Macy, one of our large department stores, published an advertisement urging Mr. Averageman to have two winter overcoats; a light one for mild weather, and a heavier one for freezing days. The last lines in this advertisement read as follows: "Be comfortable and healthy. Have a topcoat, and a heavy coat. And a raincoat, umbrellas, rubbers, and a family physician, to boot!"

Such then are the problems with which we are faced in commercial health advertising. They demand and deserve the attention of our best public health administrators and diplomats. I sincerely hope they will be accorded all the careful thought they merit. We stand to gain much by their competent solution. Our greatest hazard lies in our being indifferent, antagonistic, and negativistic toward them.

Dental Survey of Hawaii

A SURVEY of the dental program in the Territory of Hawaii has recently been completed by Dr. Guy S. Millberry, Dean of the College of Dentistry, University of California. This survey has been published by the Territorial Board of Education and copies are available at \$1.00 each, through Dr. Millberry's office. This is probably the most extensive dental hygiene survey ever made in western United States, if not the entire country. Its findings are of great interest to school administrators and public health officials.

Preventive Trend in the Practice of Medicine*

GORDON BATES, M. D.

General Secretary, Canadian Social Hygiene Council, Toronto, Ont.

THE trend of medical practice toward prevention is inevitable and it behooves the average citizen to study carefully the means to this end. The reason lies in the fact that the possibilities in the direction of prevention by the application of scientific knowledge are very great. It should be obvious even to the most superficial observer that this is the consideration which will bear the greatest weight in the determination of the type of medical practice which will prevail in the future. The common good will unquestionably be the criterion of adjustment. How radical that adjustment will be remains to be seen.

The traditional type of medical practice is based on the possibilities of cure. Up to the last 50 years little thought was given to prevention because there was little knowledge of how to prevent. Today our point of view is changing with the increase in our scientific knowledge. We know that, largely as the result of the application of the work of Pasteur, about 18 years have been added to the expectation of life in a little over 50 years. Some of this has been due to the application of scientific knowledge in ordinary medical practice; much of it has resulted from communal action in which the health officer—usually a physician, working in a profession the practice of which is so unlike ordinary medical practice that he may be said to be a member of a new profession—plays a very great part.

Today we attempt to ascertain how much more remains to be done and how it is to be done, particularly the part which is to be played by the medical practitioner—using the term in its accepted sense. That much remains to be done cannot be gainsaid; nor the tremendous social significance of the task and its achievement be denied.

Illness is too prevalent and preventable illness and postponable death are too costly. Investigators tell us that 2 per cent of our entire population is constantly suffering from disabling illness. Irving Fisher estimates that 2.5 per cent of all workers in the United States are constantly ill. An English investigator estimates that workmen

* Read before a Special Session on Preventive Medicine of the American Public Health Association at the Fifty-ninth Annual Meeting at Fort Worth, Tex., October 29, 1930.

in England average 1.2 weeks of sickness per man per year. Dublin estimates the total capital value of lives which can be saved annually through the application of modern preventive medicine and public health measures at over 6 billions of dollars. An estimate by Rankin¹ is as follows:

\$ 2,500,000,000.00	for treatment of diseases
2,000,000,000.00	loss from decreased wage earning capacity
6,000,000,000.00	loss of wage earning capacity through postponable deaths

Total \$10,500,000,000.00

This is one-ninth of the total annual income of the United States, estimated at 90 billion dollars.

Proportionate figures would apply to Canada. In view of the fact that the dollar yardstick is the most widely accepted means for ascertaining the purport of social statistics these figures are significant, particularly when it is realized that perhaps 50 per cent of our illness is preventable and 30 per cent of our deaths are postponable.

Granting the relationship of the health officer to all of this—what has it to do with medical practice?

I think that it was Dr. George Vincent who coined the prophetic phrase "The practising physician is the ultimate health officer," and one must immediately acknowledge that in some cases there is a clear-cut relationship between the cure of a disease in the individual and the prevention of its spread to others. This applies to all of the communicable diseases. The pediatrician, however, has been the first to apply preventive medicine deliberately in his everyday private work. Transferring the activities of the well baby clinic to his consulting room he not only advises as to the diet and general care of the apparently well child but as to all methods which may be employed to prevent preventable ills. Vaccination and immunization against diphtheria he utilizes as an obvious duty rather than waiting to treat the diseases which may result if he neglects them.

Possibly such methods are evidences of a trend which will show itself also in the consulting room of the general practitioner. Judging from our communicable disease statistics the time is not yet. All children are not cared for by pediatricians, and in spite of the fact that toxin-antitoxin and toxoid are available for immunization there is far too much diphtheria, although most creditable showings are made by some cities in which carefully planned campaigns have been carried on. Indeed in some cases the incidence of diphtheria has been reduced almost to zero.

A difficulty in connection with this problem lies in the fact that the greatest mortality is in the ages between 2 and 5. While organized

health departments have little difficulty in dealing with the school age child, these younger children constitute a class with which it is harder to get in touch. One cannot but feel that a plan should be developed here which involves new machinery. Possibly in the utilization of the services of the family physician lies the solution of this as well as other health problems.

It has been pointed out by statistical experts that not only is it true that prevention is of advantage to the community but that the physician may ultimately feel its monetary advantage. It seems paradoxical, but actually utilizing the services of the general practitioner and granting a reasonable scale of remuneration for his services, the total elimination of a disease such as diphtheria would cost the state less than it is paying now in doctors' fees, hospitals and deaths. At the same time the physician would probably profit more than now.

I am informed by Dr. Henry Vaughan that in Detroit through a generally adopted coöperative scheme between the Health Department and the profession a program of general diphtheria immunization is well under way. It has been necessary to adopt a standard fee for the immunization of non-indigents, a slightly smaller fee to be paid by the city for indigents. Of course a general campaign of public education has been necessary. One need not go into the details of this plan here but it would seem that such a scheme, or a modification of it, should be applicable almost anywhere. In connection with the Detroit scheme public health nurses have been sent into districts with high diphtheria rates to urge immunization for all children between 6 months and 6 years of age. In one area, out of 900 children between 6 months and 2½ years, 800 were immunized within 30 days. All of this work is done by the coöperating family physician, not by the Health Department direct.

The same principle in a modified form has been adopted in other places. In East York, a township near Toronto, 7,000 children, school and preschool ages, were immunized by the local practising physicians. This work was done in school buildings at a fee of \$.25 per child, paid by the municipality, dealing with as many as 200 an hour.

There are other phases to the adoption of preventive methods by the general practitioner. There has been a decline in death rates and an increase in the average duration of life during the last few years, largely the result of the reduction of mortality rates in childhood, and largely the consequence of organized public health methods. Infantile mortality rates have fallen and steps have been made towards the eradication of the communicable diseases.

Unfortunately little seems to have been achieved in the direction of cutting down mortality rates in the later decades, in which particularly incipient conditions neglected may proceed to a serious or fatal issue. An infected tooth—relic probably of the period previous to preventive dentistry—if not removed may be followed by all the dire results of focal infection. Mounting blood pressure, cancer, tuberculosis, or a positive Wassermann reaction neglected, means disability or death. Bad habits, too little or too much exercise, worry, overeating, heavy drinking, and overwork, all are conditions not followed necessarily by immediate symptoms, although the end consequences may be serious. Generally, the physician is consulted too late. His services are too frequently not nearly so valuable as they might have been had the consultation been earlier. The lesson is obvious and the cure—periodic health examination.

About 2 years ago, through the coöperation of the Dominion Department of Health and the Canadian Medical Association, a standard form for the examination of the apparently well was printed and sent to every physician in Canada. The number which has been used is problematic. The need is obvious; and yet the physician trained in the curative school frequently looks askance at the prospective client who in answer to the question, "What is your complaint?" is unable to provide a description of an ache or a pain. The public, still unaware of the advantages of the scheme, on the whole stand aloof. The need for two educational programs—one for the public and one for the physician—is obvious.

A recent Canadian scheme involving the coöperation of several large life insurance companies with the Canadian Medical Association to the end that certain policy holders may be examined by their own family physicians, using the standard form, is at least an educational gesture of value.

There are other reasons for the development of a preventive program. I have suggested that curative medicine as it is now practised has its inevitable connection with prevention. In a Milwaukee 1-day survey it was found that less than 40 per cent of the sick people had a doctor in attendance. Again in a survey conducted by the Metropolitan Life Insurance Company it was shown that members of large families cannot pay so much for medical care as those in small families. Persons living alone paid out an average of \$75.63 in 6 months for medical care, whereas those in families of 9 or more paid out only \$6.64 during the period. The effect of this situation is, of course, to throw the members of the large family of the type surveyed in this group upon the mercies of the community. Hence the clientele of the

free clinic, and what may well be termed the exploitation of the physician.

One cannot on this occasion go into this phase of the question at length, but it should be said that this and similar considerations have in most civilized countries forced public attention to the question of health insurance. Health insurance is probably inevitable on this continent and its coming will exert a profound influence on the progress of preventive medicine. In Canada, a Royal Commission has brought in a special report on the subject in British Columbia, while in Alberta an inquiry by a Special Committee of the Provincial Legislature will probably have far reaching results.

There are other developments which have their influence on medical practice. The health unit program in both Canada and the United States is spreading very rapidly, with a marked result in the direction of diminishing rural death rates. In Western Canada the travelling clinic maintained by the government has been developed for the purpose of providing dental and surgical service for the correction of defects among school children. This clinic, self-contained, moves by motortruck, operates in schoolhouses or other suitable buildings, and the staff lives in tents. Operating in the more scattered districts of this province it is said to carry its service to persons who otherwise would be uncared for in this regard. A moderate fee is charged.

Another development which is having its influence on medical practice is the plan in Western Canada (Saskatchewan) where certain areas operate municipal hospitals and employ municipal doctors. Seventeen rural municipalities in this area employ doctors on a full-time salary of \$3,000 to \$5,000 yearly, who give free medical attention to all and undertake the general public health work, such as school inspection, vaccination and diphtheria immunization as well. This is, of course, pure State medicine.

One might also here discuss the pay clinic and its various advantages and disadvantages. There are unquestionably many developments in medical organization at this time which illustrate the trend toward prevention and its reasons. The fundamental factor which is responsible is unquestionably legitimate public demand. Manufacturers and employees alike—indeed, our general citizenship—are rapidly realizing the profound social significance of neglected illness and neglecting the prevention of illness. It is so great a problem that no country can afford to ignore it.

Influences which tend to oppose this trend must be frankly described as reactionary. I believe that the action of a well known local American medical society in expelling a distinguished neurologist

because of a perfectly legitimate transaction with a physician of whose activities as a director of a pay venereal clinic, the society happened to disapprove, was a demonstration of one of the most objectionable phases of medical trades-unionism. I say this in the belief that trades-unionism in its accepted sense is a good thing.

Similarly one cannot but feel that the public address by a distinguished British pediatrician at the recent meeting of the British Medical Association, in which he attacked education of the public in health matters as well as the idea of periodic health examination, was but a demonstration of another reactionary trend, giving the critical observer interested in public health the opportunity for caustic criticism of the passive resistance of the clinician to public health ideas. This kind of thing, it seems to me, makes a very bad impression on the thinking public.

One cannot but feel that where communities are planning health programs the first group to be consulted should be the medical profession, but it is also true that the first group to lead should also be the medical profession, the members of which should exhibit the greatest concern at high sickness or death rates. A specific suggestion here is to the effect that in local health boards representation of the profession and of the medical teaching bodies in the larger cities would be a means of giving practical expression to this spirit which is unquestionably latent in the profession at all times.

A medical philosopher once said that the medical profession constantly tends to eliminate itself. This statement is only true to a degree. The profession tends to adjust itself to new conditions and adjustment must in the long run be in the direction of the greatest good for the citizen in whose welfare the practice of medicine plays so great a part. The advocates of individualism and the opponents of paternalism may have some truth on their side, and in the rapid development of this day and age we must not forget the virtues of what we have. I believe that the final form in which medical practice will crystallize will be determined by the part it can best play in insuring for humanity that in following generations there may be healthy childhood, robust maturity and an ever greater number of citizens enjoying healthy, efficient lives for an ever increasing number of years.

Preventive Medicine in Private Practice*

WYMAN C. C. COLE, M. D.

The Children's Clinic of Detroit, Detroit, Mich.

IT is the purpose of this paper to discuss preventive medicine from the point of view of the practising physician, and especially to consider the relationship between the health officer and physician in regard to this subject.

The fact that we are holding such a symposium, suggests that there are certain conflicts between these two groups, or at least that they have failed to coöperate properly at times. Whatever differences there may be between the practising physician and the public health official, I think are overestimated, and when present are due largely to varying points of view. This symposium further indicates a desire to eliminate any possible differences which may exist. This is, of course, absolutely essential before any real progress can be made in preventive medicine.

It is true that there exists a certain suspicion in a considerable element of the medical profession of certain public health activities. This is based largely upon the erroneous notion that these activities are encroaching upon the practitioner's field and if continued will result in loss of practice and consequent loss of income to him. The fear of State medicine is constantly present and while properly conducted public health work should not be confused with State medicine, sufficient tendency in this direction has been shown in certain localities to warrant suspicion. The thinking and progressive men in medical practice do not fear State medicine.

It is obvious that some development in medical practice is necessary to extend adequate medical service to every member of the community, and to adjust the present economic imbalance between income and the cost of medical care. What physicians are anxious to do is so to guide this development as to avoid the socializing influences, the initiative destroying and paternalistic effects, the political complications, and other numerous dangers which have appeared where State

* Read before a Special Session on Preventive Medicine of the American Public Health Association at the Fifty-ninth Annual Meeting at Fort Worth, Tex., October 29, 1930.

medicine has been tried. Extreme conservatism must be applied in making such vital changes in our social structure. The practising physician is just as much interested in extending medical services and knowledge as is the public health worker. It seems that further co-operation toward the development of methods of reaching our individual and collective goals is what we are trying to attain.

Undoubtedly the chief difference between the physician and the health official is that the former deals with the individual and the latter with the group, but we must not lose sight of the fact that the group is made up of individuals. The physician is interested in the health and well-being of his patient as an individual. How he compares with the norm is of little significance. He knows him personally. He knows his background, his social status, the details of his life. He is successful in so far as he helps this individual to better living. The health officer thinks of his work in terms of cases per 100,000 of population. He visualizes his community on a chart. Curves of birth rates, death rates and disease incidence largely indicate his success.

The physician is dependent upon his patients for a living. How well he cares for them and pleases them, determines to a considerable extent his income. In other words, the quality of his work determines his individual success. This is the one vital point which must not be changed with any developments in medical practice, and is the one overwhelming and so far unanswered objection to State medicine. When we take away from the practice of medicine the direct responsibility of the physician to his patient, it will be a sorry day for the patient.

The health officer on the other hand is independent of his group, and unfortunately in many communities is dependent upon his ability as a diplomat and politician for his success. He may be the best health officer in the world, but unless he can make his local officials think so, he may be out of a job. There is consequently a natural tendency to make a showing, rather than to do the most work where it will do the most good, and the annual report becomes a thing of great moment.

Physicians are naturally conservative. If they are not, they soon become so, if they wish to succeed in private practice. We all admire the man who does a piece of revolutionary research, and much of our progress depends upon his enthusiasm; but when we are sick we want a man with plenty of experience and a reputation for caution. We are willing to have the new things tried on some one else. Physicians consequently take to new things and new ideas slowly. They cannot recommend procedures to their patients until their merit has been

shown conclusively for, not only often, but usually, the new discovery of today is the failure of tomorrow.

Health officers on the other hand are likely to be progressive. New things and new methods appeal to them. This is as it should be, and under ideal conditions the two groups should balance one another.

Most of the lack of understanding and potential conflicts between health officers and physicians are based upon these differences in point of view. Therefore, they are not real or vital and can be readily eliminated by more intimate relationships and more frequent exchange of ideas. A proper adjustment of these viewpoints will certainly be to their mutual benefit, and will be necessary to the achievement of any permanent program in preventive medicine.

While preventive medicine is by no means new, our conception and application of it have changed greatly in recent years. Many of the new phases are still in a very formative stage, and we are sometimes not certain as to proper procedure, but the ideal of preventive medicine is here. The public does not have to be sold to it but is eager for it, and it places a great responsibility on us to know how far we can safely go without destroying that ideal and the confidence of the public. The physician of the future will give much of his time to purely preventive work. Already our organization devotes at least one-third of its time to this type of practice and we regard it as only the beginning.

I wish to discuss briefly the relationship between the health worker and physician to two phases of preventive medicine with which as a pediatrician I am especially familiar. These are routine prophylactic examinations, and immunization against contagious disease. The general principles involved here are doubtless the same as in the various other phases of preventive medicine.

We can assume without any argument the desirability of extending these two things to our entire child population. No intelligent person could question the merit and overwhelming benefit of such work after even the most casual inspection of our vital statistics during the past 50 years.

Having taken for granted that this work is worth our very best efforts, we are interested in working out methods of furthering it and especially of determining the relationship between, and the relative responsibilities of, the health officer and physician to this type of work. I cannot see that this is a problem which should give us any particular trouble. The functions of these two groups are fairly definitely established and from what I know of both, neither has any desire or intention to encroach upon the other's domain.

As brought out earlier in this paper, the function of the health officer is general to the community as a whole, the function of the physician is specific to the individual. The essential work of the health officer and public health worker is to keep records of the health of the community, to organize and carry out methods of improving that health, to distribute information which will arouse the interest and increase the knowledge of the community in its health, and to conduct such clinics and health centers as are necessary to arouse popular interest and to care for those persons unable to provide this type of medical care for themselves. The work of the physician is of a much more technical nature. He is interested in the scientific aspects of medicine and not in its organization. His work is to study and advance medical science, to examine patients, and to apply that scientific knowledge to them, and to give them individual and collective advice for the improvement of their well-being. The average physician must do this work through the daily contact with the individuals of his practice and to some extent through coöperation with public clinics.

The chief criticism I have to make of this work, as done by both health officers and physicians, is that they do not do nearly enough of it. The more child welfare work is developed, the more of it there is to do. In communities where there are no clinics and where the physicians show little interest in prophylaxis there is little or no demand for such service, but where clinics are common and physicians interested, the demand increases steadily. The type of clinic referred to in this discussion is not the hospital or the private physician's clinic, but those public ones whose aim is prophylactic and educational.

Such clinics have been criticised by physicians at times for certain reasons: (1) the fear that they would take business away from the doctor; (2) because they are not always careful in controlling the social groups admitted; (3) because they frequently extend their work to include the care of sick children; (4) because at times certain nurses and social workers have been indiscreet in disparaging the work and merits of physicians in their community.

It is extremely shortsighted for any worthwhile physician to think that a well conducted prophylactic clinic in his community can do him personally anything but good. Patients whom he would care to have among his private clientele will not attend a public clinic if they are able to afford his service, provided he gives them the same or better service. Every patient who is well cared for in a clinic will be the cause of several going to a private physician. The better and more completely the public health clinic in his neighborhood is conducted

and the more interest he shows in its success, the better educated in health matters that community becomes and the greater the physician's individual success. Wherever infant welfare work has been well conducted, there pediatricians flourish, and the same principle applies equally to the other branches of medical practice.

Clinics, of course, must be careful of the social status of persons admitted. Health workers are as well aware of this as anyone and offenses are isolated instances and not general. Financially competent persons who are willing to attend a free clinic are probably the type who would not pay their doctor's bill anyway.

The criticism that prophylactic clinics frequently care for sick children, however, is a serious and just one. Nothing but well children should be admitted to such a clinic. The minute we begin to take care of sick children in a well baby clinic, we begin to do poor prophylactic work and much worse therapeutic work. It is true that we find it difficult to turn away a sick child, but that is another problem and must be handled in a different way. This is an offense frequently committed and will do more to arouse the antagonism of physicians and destroy the confidence of the public than almost anything else.

If it is shortsighted of physicians not to appreciate the value of clinics to them, how much more is it shortsighted of social workers to criticise and depreciate the doctors of a community. Of course, only thoughtless persons would ever do this. If these will remember that the physician is much more deeply entrenched in the confidence of the public than they can ever hope to become, they will be more careful. No physician, however reactionary and uncoöperative he may be, can afford to be antagonized as long as he is sincere, and a few kind words about him and to him will usually convert him from an opponent to a supporter.

Lay organizations which foster and carry out public health activities are the chief offenders along these lines, because their policies are often controlled by emotionalism and conscious altruism, rather than careful consideration of facts. One point which I wish especially to emphasize is that all public health clinics should be supervised by the best medical talent available. The staff should be largely young men and those desirous of obtaining training; but at the head must be an outstanding man to direct and train that staff. If this is well done, not only is the work of various clinics unified but the standard of practice will be set for the whole community.

The problem of immunization against contagious disease is controlled by essentially the same principles as already discussed, and seems to me a very simple one. There is no question about the de-

sirability and urgency of having every child immunized against diphtheria and smallpox. This problem again is divided into two parts—selling it to the public, and its technical administration. The first is in a large part the work of the health official, which he is in a very strategic position to put over, through all varieties of advertisement, circularization, canvassing, and general methods of propaganda. Most of the public can be influenced in this way, and the remaining doubters can usually be convinced by a word from their physician. Nothing more is necessary to fulfil our objective in this program than to give it our sincere and constant attention.

The technical administration of these prophylactic measures is, of course, a purely medical function and must be done with care unless we wish to run the risk of antagonizing the public. Nothing will serve to offset our most complete publicity efforts like the poor handling of this phase of the work. Toxin-antitoxin and vaccination must always be administered under the supervision of a physician. The herding together of large numbers of children in clinics or schools to carry out these procedures without giving thought to the condition of the individual child will result in the antagonism of a large group of parents. This is as much a medical procedure as the removal of tonsils or the regulation of diet, and at least a superficial physical examination must be given in every instance.

We have made it a policy for several years not to carry out these procedures on patients who came to us asking for them without giving an examination. It is surprising the frequency with which conditions are present, which if not explained might give an erroneous and harmful impression to the patient. I am sure that this has had a great deal to do with establishing the confidence of our patients in the procedures and in us, and has rendered it increasingly easy to sell prophylaxis to our clientele. While we may feel that scientifically little harm is likely to result from administering these things to even quite sick persons, it is very difficult to convince laymen of it, and much wiser to avoid the necessity of so doing. In so far as possible, toxin-antitoxin injection and vaccination should be done by the family physician. Only where persons are financially unable to pay for it should clinics be used, the same as with any other medical procedure.

It should be mentioned for the benefit of those who may think otherwise that preventive medicine is just as much a medical service as is mending a broken leg or delivering a baby; it requires just as much or more training and clinical skill; and as such is entitled to a corresponding fee to the physician. Properly carried out preventive medicine is of more value to the community than therapeutic medicine

and fully as worthy of satisfactory financial reward. We have no trouble in getting our patients to pay well for such service.

I wish to make just a brief comment about the necessity for conservatism in public health programs. We must not go before the public with definite recommendations until we are absolutely sure that the things we are recommending are true. In our enthusiasm to improve conditions we may do more harm than good unless we are on firm ground. What I mean can be well illustrated by the effect which the nutrition clinics, which were so popular a few years ago, have had. While very little, if anything, has been done to improve actual nutritional conditions those of us who are in private practice know that a great many serious psychiatric and behavior problems have resulted from the excessive and ill-guided interest of mothers in nutrition.

At the present time considerable interest in mental hygiene is being shown and clinics of this type are being established in increasing numbers. This is splendid from an experimental and scientific point of view, but must not be sold to the public as a sure thing, because in another decade our views will doubtless be very different. Much splendid work concerning the prevention of scarlet fever has been done in recent years and our anxiety for a method of controlling this disease is likely to bring us before the public with procedures which are not tried. Those of us who have tried scarlet fever prophylaxis know that it is very imperfect, and unless we wish to prejudice the public against it, we had better confine ourselves to further experimental work for the time being.

In summary, then, let me say again that I can see no cause for conflict between the health officer and the physician. The function of the health officer is to organize, to advertise, and to supervise public health activities. The function of the physician is to develop and apply medical science. Only by complete coöperation between the two groups will the realization of our ideals of public health be attained.

Tularemia

RECENT reports to the U. S. Public Health Service indicate that an unusually large number of cases of tularemia are occurring this winter. Because of economic conditions, rabbits form an important article of diet for a number of persons in many sections at the present time.

Although a new disease of man, tularemia has now been recognized in 43 states, in the District of Columbia, Japan, Canada, Russia and Norway.

European Methods of Attacking the Disease Prevention Problem*

RALPH A. REYNOLDS, M. D.

Stanford Medical School, San Francisco, Calif.

THE medical and public health systems existent today in the United States present certain aspects which are unsatisfactory on the one hand both to the general public and to the far-sighted public health official, and on the other to the practising physician.

Active and effective prevention of preventable disease is today the keynote of any intelligent public health program. The leaders in preventive work have been for the most part public health officials. Supporting them in their aims is the majority of the lay public. More and more are the American people awaking to the possibilities of a higher level of health through active prevention, and more and more is the popular demand for good medical service at reasonable rates being accompanied by the additional demand for more expert assistance in keeping well.

That the efficiency of our preventive work does not even approximate its possibilities is illustrated by such facts as the following: constitutional diseases, such as heart and kidney disorders are definitely on the increase; nervous and mental disorders are increasing at an alarming rate; syphilis and gonorrhea remain fairly general, especially in rural districts. We have still 40,000 cases of smallpox annually, and the incidence of diphtheria is much greater here than in many other civilized countries. Our maternal and infant mortality rates give us no cause for pride. In 1927 our maternity mortality placed us low in the list of all nations compiling data on this subject. For every 10,000 live children born, 65 women lose their lives from causes connected with childbirth. Our infant mortality rate also suffers by comparison with that of many other countries.

These are some of the conditions which our public health officials wish to remedy, and the remedying of which our lay public is beginning to demand. To accomplish the task under our system would require the unified work and complete coöperation of all private practitioners.

* Read before a Special Session on Preventive Medicine of the American Public Health Association at the Fifty-ninth Annual Meeting at Fort Worth, Tex., October 29, 1930.

Meanwhile the private practitioner is confronting certain problems of increasing difficulty. First and always present is the difficulty of collecting bills, the worry of making a living. Second, he now finds his practice increasingly encroached upon by the free or institutionalized medical services of state or city governments and of various organizations. The high cost of health service is causing free clinics to extend their fields of activity more and more into the middle classes, while the failure of many private practitioners to carry on preventive work and to coöperate with public health officials is making it increasingly necessary for public health departments to extend their services into fields formerly held sacred to private practice.

On both sides, then, is cause for dissatisfaction. Is it reasonable to believe that under our present system an adjustment satisfactory to all can be made? Can private practitioners remain as they have been in the past—each to his own patients the individualistic dictator of health standards, of medical costs, of prevention or non-prevention? Meanwhile can he keep his private practice intact in the face of new popular demands? Is it probable that private practitioners will unite in a coöordinated, purposeful program for enforcing the policies of their public health officials?

In brief, can we expect to see the problem solved under our present system by complete coöperation and unification of aims? Without doubt we all should like to answer, yes. I, personally, can find no reason to support such an optimistic outlook. The intensity of the conflict and the difficulty of the problem show signs of increase rather than decrease. Furthermore certain elements inherent in private practice make the accomplishment of a unified and efficient system of preventive medicine highly improbable.

First, our much cherished individualism in private practice deprives the public of the advantages of unified effort under expert direction. Only the man of exceptional vision and ability is capable of seeing the possibilities of active preventive work and of causing those possibilities to materialize successfully. The majority of our private practitioners, like the majority of all men, are not gifted with exceptional vision and ability. Acting individually then, they cannot be expected to add greatly to the accomplishment of important preventive work.

Second, the average private practitioner feels that he can spare no time nor effort from the pressing business of building up and maintaining a routine practice. To carry active, educational preventive work into the community as a whole requires time and effort which the practitioner feels must be necessarily applied to the routine of making a living. This daily necessity of maintaining a practice automatically

places the emphasis upon curative rather than preventive medicine, and to the average practitioner the preventive phase is consequently comparatively uninteresting and remote.

I can see no hope of these factors undergoing any significant change, while human nature remains human nature. It is a significant fact that those countries which in recent years have made marked improvement in the health of their people have done so not by trusting to individual effort but by means of unified organization under effective leadership.

The city of Vienna, under its liberal government, has created a centralized public health system which already has accomplished remarkable results. Health direction is carried out by district supervisors, each of whom ascertains at regular intervals the health conditions in each family in the district. Not only does this supervisor recommend to the family what needs to be done; he has also in certain fields the right of enforcement for which our own public health official so often longs in vain. The Viennese child, for instance, who is found to have a physical or mental defect needing curative treatment is promptly taken over by an appropriate institution. School physicians and nurses coöperate in reporting problem cases and physical defects to the district supervisor, and prompt study and treatment of these under government agencies is a matter of routine. In spite of the poverty of the Viennese, the level of health among their children is today exceptionally high.

Within 8 years, Vienna has reduced the incidence of congenital syphilis by more than one-half. Government supervision and education have resulted in practically all pregnant women receiving Wassermann tests and treatment when indicated. Today over 70 per cent present themselves for this service before the 4th month of pregnancy.

Soviet Russia is demonstrating in a similar way the effectiveness of active, centralized health control. Within less than 10 years, over the whole of Russia the infant mortality rate has been reduced by more than one-half, in spite of the poor means of communication, the ignorance of the people, and the size and varied nature of the country.

Before the institution of the new public health régime, Russia's rural districts had no public health service. There was in these districts only 1 physician to every 20,300 peasants. Today the centralized government health service has arranged for a more equable distribution of physicians and has so organized the work of clinics, nurses and social workers that 5 times as many rural communities now receive a fair degree of public health service as in 1918. This extension of medical work into the rural districts so rapidly and efficiently

accomplished under centralized government control is of special interest to us in this country, where many of our own rural communities present a crying need. President-elect Hugh S. Cumming estimates that 75 per cent of our rural districts are without adequate public health service. Lacking centralized direction, the medical profession to a constantly increasing degree is congregating in the cities. It is hard to see how any agency short of a centralized and powerful health organization will be able to remedy this condition.

The superior efficiency of such an organization acting comprehensively with government authority is apparently recognized throughout Europe. Most of the important European countries have taken steps in this direction, France being, I believe, the latest to adopt such a plan.

In this country, as has also been the case in European countries in the past, the idea of government control of medical work arouses bitter opposition. The advantages, however, of the unified system can hardly be denied and its possible disadvantages may perhaps be overestimated. Most often, one hears the statement that State medicine would kill ambition and reduce to an inferior level the quality of medical work. In those countries which have adopted the new system I have been unable to find any evidence of any such deterioration. Why should it deteriorate? Those men who make the real contributions to science are almost without exception the ones whose ambition is scientific, not pecuniary. Much of the best public service is performed by men whose interest is in the work itself and who gain nothing from it in a material way. Rather than quenching scientific ambition, I am inclined to believe that the new system gives it greater opportunity. Relieved of the distraction and worry of working up a paying practice and of attempting to collect bills, the physician is in a far better position to pursue an ambition for research or for community health leadership.

In a prosperous nation like our own the physician under a government health program might expect for his services: an adequate salary, an old-age pension, funds and equipment for research, and a periodic leave of absence for postgraduate study. I am inclined to believe that the medical men whose ambition could not flourish under such conditions are those whose loss would be no great blow to the profession.

Be that as it may, our present dual system is failing to accomplish many things which are being accomplished elsewhere as a result of unification. Our public is becoming aware of this fact and is dissatisfied. Our public health officials find their hands tied in many

ways, and are also dissatisfied. If unification and efficiency can be accomplished without changing our system, all concerned will welcome the solution with joy. One fact remains, however, uppermost and insistent. Whatever adjustment may be necessary, whatever sacrifice of personal inclinations—unification of aim, efficiency of public health service and a tremendously increased effectiveness of preventive work must in some way be accomplished.

Administrative Control of Commercial Blood Donors

FOR the first time, so far as we are aware, the practice of commercial blood donors and blood donor agencies has been taken under administrative control by the health authorities, the pioneer step being due to the Board of Health of New York City. Hereafter, in that city, no commercial blood donor or blood donor agency may operate except under a permit from the Department of Health, and subject to the regulations adopted by the Board.

This is a commendable advance, for the keen business competition between some of the agencies was beginning to result in such wholly unsatisfactory and even dangerous conditions that the practice of transfusion was seriously threatened.

Investigations carried on in New York City showed that in some cases the blood of donors was incorrectly grouped, and instances were discovered in which the donor's blood gave a 4 + Wassermann reaction. In some cases excessive quantities of blood were withdrawn without the knowledge or consent of the donor, and too frequent use of a particular donor was permitted.

Judging by the regulations adopted by the New York City Board of Health the occurrence of such evils should hereafter be impossible. The tests for blood grouping are entrusted only to recognized laboratories, the luetic tests are made by the laboratory of the Department of Health. No donor is accepted for registration by the Department of Health until after a physician's examination shows him to be in good health, special attention being paid to syphilis, malaria and other communicable diseases. Each registered donor receives an official pass book containing his photograph and personalia, together with a record of the blood group to which he belongs. A record of every transfusion in which this donor participates must be entered in this book, as must also a record of the regular medical examinations prior to transfusion which the regulations demand.

In its announcement of the new requirements, the Department of Health acknowledges the coöperation of the New York Academy of Medicine, The County Medical Societies, and various eminent authorities, including Dr. Karl Landsteiner, in the preparation of these regulations.

Public Health and Private Practice *

GEORGE C. RUHLAND, M. D., F. A. P. H. A.

Commissioner of Health, Syracuse, N. Y.

WHY can there not be more harmony and good-willed coöperation between public health agencies and the private practising physician?

It may be considered imprudent and in questionable taste to suggest that all is not well in the affairs of the family of the medical profession. However, it is already an open secret, and therefore no betrayal, that public health and private practice are living in more or less strained relationship, and that there have been family rows.

It seems much wiser, under the circumstances, to deal frankly with the situation, examine the conditions that apparently lead to friction, and discuss them dispassionately with a view to peaceful settlement—rather than allow matters to drift until irreparable damage is done.

There should be good will, harmony and coöperation between public health and private practice, of course. Are they not both concerned in the protection of public health? do they not speak the same language? employ, more or less, the same technic? and recruit their membership largely from the same professional groups? Is their work not dependent upon one another?

All this is admittedly true. All this may be considered as good reason for team work. However, the facts are—as practically any health officer must admit if he is perfectly frank about it—that his own service, or that of public health in general, has come at some time or other under the criticism, at times bitter, of his professional colleagues in private practice.

Dr. Olin West, who, as Secretary of the American Medical Association, unquestionably speaks advisedly, has with admirable reserve this to say on the relationship of public health to private practice: "There is a certain element of the medical profession inclined to withhold its coöperation with departments of health.¹ There are reasons for this, and some of them not in any manner due to faults of the medi-

* Read before a Special Session on Preventive Medicine of the American Public Health Association at the Fifty-ninth Annual Meeting at Fort Worth, Tex., October 29, 1930.

cal profession, but originated in certain official actions taken by the departments of health themselves."

It would seem idle, or worse, with such evidence to deny the existence of difficulties, or to try to waive them as inconsequential hospital corridor gossip of a disgruntled few. Nor does a policy of "Let us not talk about it," in the hope that conditions will right themselves seem sound and reasonable. We might as well believe that a policy of earnest wishing, or Couéism, will solve the cancer problem for us.

The very persistence of symptoms of dissatisfaction should be a warning that there is a real and deep seated malady. As physicians and health officers, we should bestir ourselves to determine the cause or causes of the trouble, and then proceed to corrective or curative measures, if possible. An inquiry must be an obvious first step in the direction of better understandings, and better working relationships.

The reason for the cry of distress and protest that comes from the ranks of the medical profession seems fairly clear. It is a question of bread and butter, or a fair chance at making a living. With an average annual income of scarcely more than \$3,000⁷ the practitioner of medicine finds himself poorly compensated for his 6 or 7 years of preparation and training. He finds it difficult to meet his overhead for office equipment and necessary running expenses; to provide for his family, to give his children the education he wants for them; to carry insurance; and yet save enough for the rainy day.

Is public health service alone to be held accountable for the disadvantageous position in which the average practitioner of medicine may find himself? Hardly. The economic factors that distress the medical profession manifestly affect others as well, and call for a new adjustment all around. Cannot part of the profession's difficulties be explained by the fact that, "We live in an economic age, but medicine as an organized profession does not fully realize it?"⁸

Cannot part of the economic difficulties of the medical profession be corrected by changes in the present methods of medical training? Cannot some of the neglected fields of therapy be regained for the profession? Cannot medical ethics unbend to permit the specialist in medicine to announce frankly his particular field of service to the public? Cannot group medicine,⁹ help solve the cost of overhead, and offer more efficient service at a lesser cost—especially when operated in a manner worked out by Crampton?¹⁰

Perhaps it may seem somewhat forced, in a paper that proposes to discuss the relationship of public health and private practice—and more particularly factors that apparently are causing difficulty between these two—to suggest a line of inquiry that might prove helpful

to the medical profession. It certainly is not done with any intention of diverting attention from the main issue. It is done, however, frankly for the express purpose of making it clear that there are obviously quite a number of other causes that have to do with the economic difficulties of the medical profession, and that—whatever irritation arises therefrom—this cannot be solely charged against the activities of health departments.

There is a gradual encroachment in various directions in the field of medical practice, which takes the form of group practice, public clinics, pay clinics, organization of hospitals and medical service by great corporations such as the railroads and industries, student health services in the universities, benevolent societies with hospital privileges; and public health is constantly extending its range.³

This listing of factors that unquestionably affect the interest and income of the individualist in medicine leaves out self treatment by the public, the activities of quacks and various cults; and does not mention the fact that a large portion of the population finds it difficult, if not impossible, to meet the cost of medical care. There can be no question, however, that progress in preventive medicine, and particularly in the control of the communicable diseases, has profoundly affected the income of the practising physician. "The world of medicine is today in the throes of a far reaching readjustment in which even the wisest are sometimes at wits' end."⁴

The days when a few cases of typhoid fever in the fall of the year carried the practitioner of medicine comfortably through the winter are over. Smallpox is going, so are diphtheria, malaria, yellow fever, plague, hookworm, and the summer diarrheas of infancy. The list of communicable diseases which the physician is called upon to treat is growing smaller, and with this his income from these sources. This may be lamentable from the physician's point of view. However, can any other course be justified than one that will seek prevention where prevention is possible? Is it not for the medical profession to adjust itself to the trend of the times and learn to shift, where possible, from curative medicine to preventive practice?

Health departments cannot neglect to urge and seek preventive means for the protection of the public health. After all, health departments belong to the public and are expected to be operated in the interest of all the public. Increasingly the public realizes that life and health represent economic assets; that sickness is very expensive; and that the cost of sickness, disability and premature death ultimately falls back as a burden upon the taxpayer. It is not to be wondered at, under the circumstances, that public opinion becomes more and

more insistent in demanding health protection as a community service. If any one doubts this, let him get a sample of public opinion by reading "A Patient Looks at Doctors," *Harper's Magazine*, November, 1930.

Does this mean State medicine? Who knows? It may be well to consider what Glenn Frank has to say on that point: "State medicine will not come if doctors generally, display, in years ahead, adequate sensitiveness to social values and adequate statemanship in meeting social needs."

In the meantime what can be done to lessen friction between public health and private practice and to promote better coöperation? It would seem a good beginning for the health officer to abandon the traditional police power attitude in dealing with the medical profession, and to remember that much more can be accomplished ordinarily by good-willed coöperation based upon understanding. Unquestionably much of the friction between public health and private practice results from misunderstandings. We have not always taken time to explain our plans and actions.

As for the special activities of health departments that have to do with what may be called "medical service," these can be carried out, it would seem, without friction, if it is fully understood that they are exclusive of the free treatment for the indigent sick, essentially and entirely of an educational character.

Health education, that is advising the public in general terms on matters of personal hygiene, and urging them to go to the physician at the earliest evidence of symptoms, or for periodic health examination, surely should not be met with rebuff or criticism by any practitioner of medicine.

As for the so-called "clinic services," at which expectant mothers are advised, where infants and preschool children are examined and advice for their general care is offered, these activities should remain free from any objection, provided doctors are given to understand that these after all constitute merely an educational approach by which departments of health mean to train the public in the habit of coming for periodic examinations, and for the purpose of keeping themselves under medical supervision.

It is—and this should be made very clear—in substance no different finally from school medical inspection, which as a public service surely has demonstrated its value, and which has also served to refer more children to the physician than came to his attention formerly.

Along these lines a good-willed coöperation service should be possible that will satisfy public interests and be of benefit to the practising physician as well.

Deaths of Two Men Notable for Their Public Health Work

WALDEMAR HAFFKINE, for many years bacteriologist to the Indian Government, died at Lausanne on October 26, in his 71st year. He was a Russian by birth, and was graduated from the University of Odessa in 1884. In 1889 he was invited by Pasteur to become an assistant at the Pasteur Institute. After 4 years there he was asked by the Government of India to devise methods for the arrest of cholera, and became attached to the Government Laboratory at Bombay, which in 1925 was named the Haffkine Institute, in his honor. He is best known to bacteriologists through his preparation of vaccines against Asiatic cholera and bubonic plague, both of which have been used with considerable success. Unfortunately a terrible accident due to gross neglect of ordinary precautions occurred at Mulkoyal in connection with the latter, which for a time cast a shadow over his work. Haffkine was entirely cleared of all responsibility, and it is now generally accepted that his vaccine reduces the mortality from plague when used in an epidemic. He will always be remembered as a pioneer, and as having contributed greatly to the control of two of the most deadly diseases known to man.

Christian Eijkman died at Utrecht soon after. To him we largely owe the foundation of our present knowledge of deficiency diseases, through his discovery of the ill effect produced by polished rice. In 1929, in recognition of his discoveries, he shared the Nobel Prize in medicine with Sir Gowland Hopkins. He was a Hollander by birth, and obtained his education at the University of Amsterdam, where he was for some years Assistant Professor of Physiology. In 1883, he went to the Dutch East Indies with the Colonial Army, but after 2 years was invalided home and began work as a bacteriologist. Three years later he returned as a member of a commission to study beriberi. The commission concluded that the disease was infectious, but Eijkman remained in Batavia as director of the new laboratory for bacteriology and pathology, and continued his investigations. He fed fowls on scraps from the military hospital, which consisted largely of cooked polished rice. The birds developed an obscure paralysis, the cause of which was also accidentally made clear by the refusal of a newly appointed director to give the scraps to Eijkman for chicken feed. They were then fed rice in the husk and soon recovered. Eijkman identified this polyneuritis with beriberi of human beings. Since that time, many experiments all over the world have demonstrated the truth of his conclusions.

He made many other studies on human metabolism. Soon after his return home he was appointed Professor of Hygiene at the University of Utrecht, and held this position until 1928, when he was in his 70th year. M. P. R.

Responsibility of the Personal Physician to Preventive Medicine^{*}

WILLIAM H. ROSS, M. D.

President, Medical Society of the State of New York, Brentwood, N. Y.

MY contribution to this conference is based upon personal observations and experience gained in taking a civic interest in public health affairs for the last 25 years, while engaged in the private practice of medicine, and though I have been the president of a county voluntary health association for the last 12 years and the president of my county's Board of Health, I have never had any closer connection with the administrative part of public health. Therefore, I shall speak from the viewpoint of the family physician and his relation to public health. I have said all this so that I may not be misunderstood.

When public health began to mean more than essentially a police function, a new obligation was imposed on the profession of medicine, and the doctor became the most essential factor in the final distribution of public health functions; and though the term today includes many other factors, such as social welfare, mental hygiene, industrial hygiene, old age pensions, pure food laws, control of bovine tuberculosis, school health work, voluntary agencies, foundations and health departments, the doctor is, after all, the only authoritative source of health information, and the most essential factor when taken in cooperation with all other agencies.

Let us remember that in the beginning, public health was advocated and administered by individual practitioners of medicine and that it has always been an activity of the medical profession. The constitution of every general medical society states two essential objects of organization—one, the advancement of scientific medicine, the other, the betterment of public health.

We should also remember that although discussion of the need of official organization for the administration of public health began as long ago as three-quarters of a century, most health departments, as functions of government, are less than 25 years old. Therefore, we are dealing with a comparatively new relationship of medicine and

^{*} Read at a Special Session on Preventive Medicine of the American Public Health Association at the Fifty-ninth Annual Meeting at Fort Worth, Tex., October 29, 1930.

public health. The general profession of medicine is slowly modernizing its relationships to the various health influences. Medicine has been busy curing disease, and while it slowly slipped away from close contact with public health administration, it is now slowly but steadily coming back to a coöperative relationship with all of the factors of modern public health.

Social trends brought out social needs. Laymen began to try to improve the health situation. Lay health organizations followed, and later foundations began to study health problems. Medical errors were sometimes made; emotionalism sometimes overshadowed diplomacy; laymen assumed knowledge of medicine that they did not have. There seemed to be developing an interference with the private practice of medicine—the personal relationship of doctor and patient—and out of it all grew the fear of a disturbance of personal economics, a sensitive spot to every human being. A doctor often has all the wealth that he possesses tied up in his education and his equipment to practise medicine; he has personal economic obligations just as anyone else has; he began to feel that a great emotional appeal was not only unsound but that there was an added danger of the giving of medical service without compensation. All this is mentioned for the purpose of showing the reason for the general relationship of the medical profession to public health that existed until within a few years.

In recent years mankind has more or less changed front toward disease because of the public knowledge of preventive medicine, so that the world began to look more and more to the only authoritative source of medical knowledge as the important factor in its administration and final distribution. A most important situation which confronts the medical profession today is whether the relationship work in organized medicine in its efforts to correlate health influences and to coöperate with health agencies—so that a health program can be built up in which every interest may know its limitations, responsibilities, and differences—is to be mutually respected.

Medicine is in a period of transition as to its relationships to the various factors in public health and to the preventive medicine era. The leaders of medicine see clearly the need for a new relationship.

I have made a comprehensive inventory of the health activities in every county in New York State and the relation of the medical profession to them during the last 5 years, while serving organized medicine as vice-president of the State Medical Society 1 year, trustee 3 years, president-elect 1 year, and now president. A part of the general profession has not yet seen this transition, and not having realized it, has been uninfluenced by the great changes in social conditions and

social needs. While some of the profession are apathetic, the medical profession generally is not at the present time so indifferent toward the social trends of the time and the resulting needs as many organizations appear to believe.

I do not believe that medicine is under siege. I am afraid that I do not agree with certain distinguished medical men when they say that there are intended onslaughts on medicine. Medicine is too essential to human welfare for this to be thought of seriously.

There is an increasing participation of the laity in the public health field, represented by organizations and foundations. The only reason for it is that there are unsolved health problems. Foundations have pioneered in social medical research. They have brought to light unsolved health and medical problems. Their work is a public asset, and in coöperation with the medical profession an asset to the medical profession. The work of the foundations is now a force that commands public confidence, and public opinion is beginning to ask that the health problems found shall be met.

While the world looks to the medical profession to give the preventive health service and medical care that it needs, it will accept other sources of health service if it must. Voluntary organizations and foundations naturally think along different lines from the medical profession. They are hampered neither by tradition, professional conservatism, nor a code of ethics; but an understanding of the differences, to be mutually respected, is growing so fast that one can look for full coöperation and a definite and acceptable relationship in the near future.

While one may still hear in certain places that the State has no right to do certain things—for example, hold clinics for the immunization of children against disease where the profession has not yet offered to do it—one does not hear an answer to the question—"How long must the State wait before protecting from disease its citizens for whom it is responsible?" The leaders of medicine today are asking their own profession to offer a public health program instead of waiting until other organizations are forced to do so. They are asking their profession to make use of the principle of conference in developing plans to meet health problems and then to coöperate with other organizations in the distribution of preventive measures. They are advising the profession of medicine that in no other way can the best results be obtained.

While the medical profession is essential in the solution of the unsolved health and medical problems, and while the family doctor is the most essential factor in their final distribution, this alone will not solve

the problems. The medical profession is not organized for the purpose of public health work distribution and probably never will be, yet it is its duty, and it is rapidly assuming it, to furnish all professional service and to assist in the policy of public health administration.

While everyone will, sooner or later, realize that the practice of medicine is the foundation of public health, and that public health is never separate from the practice of medicine, it is the duty of the State to furnish the equipment for public health practice and to provide for the expense of administration by general taxation. This cannot be charged to organized medicine because there is no way of making up the deficits. The profession requires the aid of government, the machinery of a health department, the educational capacity of lay associations, and the research work of foundations—all under expert medical guidance. Then each factor will be a complement to the other.

A doctor has nothing to lose in practice and a good deal to gain by coöperation with any sound preventive health program. His practice will become larger just in proportion as he adopts preventive health work. The medical profession as a whole has an opportunity to assume guidance of public health work simply by coöperating with other health agencies.

The excess zeal of voluntary organizations and their influence on governmental agencies, the giving of technical service, has aroused the fear of State medicine and the economic interference with the practice of medicine, and accounts more than anything else for the apparent cleavage between public health and the medical profession. It is fading just as the understanding grows of the real relationships between the various factors entering public health administration.

There is a new force in organized medicine in New York State known as Public Relations. It is very rapidly influencing medical opinion and formulating basic principles of relationship between the medical profession, official and unofficial agencies, and the health departments of the state government. The Medical Society of the State of New York has created a standing committee to direct it, and has been careful in the selection of the members. They are men of civic instincts who have been trained in the affairs of organized medicine and, therefore, have a conception of the problems that confront the profession of medicine and are likely to increase in the next few years. They have a conception of the obligation of the profession of medicine to advance its science; to provide for present public medical needs and their expansion as time goes on, and at the same time to maintain the virility of the medical profession.

This committee is undertaking to have adopted the principle of

conference in reaching a conclusion regarding any local health program, and then to establish a coöperative relationship in its administration, with an understanding of the responsibility of each factor. Medicine cannot honestly complain if its position becomes somewhat unsatisfactory in the eyes of the public, if it does not do this.

The Public Relations Committee of the Medical Society of the State of New York undertook to have a public relations committee organized in every county society, and this has been done. It has taken 3 years of steady effort to bring this about. The committee then undertook to have each county committee make a survey of the health activities of its county and the relation of the local profession to them. We believe that this committee is doing the kind of work that will solve professional problems, and make the profession equal to official agencies and the State in its effort to meet its responsibilities for the health of its dependents.

Serving as a member of the New York State Special Health Commission has given an opportunity to see the great change today in regard to many health interests. It must be a fundamental, social change to involve as many different groups as are represented on that commission. It includes as widely separated interests as the Department of Labor, the League of Women Voters, industrial hygiene, workmen's compensation, social welfare, old age pensions, the State Department of Health, and organized medicine. It includes every department of the state government having any bearing on health and all voluntary health organizations. The study is based upon an enlarged conception of the public health problem. It is in line with the changed front of all mankind toward disease, and perhaps the reason for this change lies in the present public character of medicine, knowledge of what can be had from health service, and such things as better living, shorter hours of labor, and more education. All these things make imperative a new relationship of the medical profession toward the broader aspects of medical practice. No activity of the New York State Medical Society is increasing so rapidly as Medical Public Relations, and the reason for it is that it meets a general professional need.

The medical profession should remove any doubt of its relation to preventive medicine in order to improve its position in public opinion. Medicine understands today better than ever before the favorable influence that it can have on all public health questions.

During the last few years of intensive observation, I have often wondered why so many of my profession lacked interest in some of our relationships to public health problems; why they were unconcerned

or sometimes mildly opposed to better organization for the administration of public health; and why they were sometimes opposed to other organizations whose purpose was the betterment of public health, which is also one of the two essential objectives of organized medicine. This is all being corrected now by the educational activity of a carefully selected and well trained committee of the State Society.

Medicine is a social function. It has always been so. It is a community obligation. It is one of the features of community life. To oppose or to fail to join with community effort in any local community is letting go to waste a resource that we need and that we could make use of to the betterment of our own profession.

Of course, we must expect that philanthropists and foundations will continue to advance health and medical projects. It is proper that they should do so. If civic effort should be blotted out of medicine, it would be as disastrous as if civic effort were blotted out of government. Government does not usually initiate public improvement but carries out that for which public sentiment asks. A long training in the civic work of a Chamber of Commerce enables me to state that many world problems are being solved in this way today that would not otherwise be solved. It is the civic duty of medicine to give guidance to these projects and to show whether they are sound.

If laymen had always taken the viewpoint that health effort had a definite relationship to the practice of medicine, there might never have arisen an apparent cleavage. There has been in the past a good deal of activity without asking for medical conference, and for this reason the medical profession has lacked some interest in public health effort. Under the leadership of the Public Relations Committee this situation in New York State is disappearing. The two important factors in public health, the medical profession and the health organizations, now realize that the gap between the medical profession and public health administration is just about as wide as that between health organizations and medicine, but an understanding is developing that is already diminishing the difference.

In conclusion, all proposals to distribute health and medical service, regardless of the ability of the recipients to pay for it, will socialize medicine, and to this the medical profession rightfully objects.

The various agencies of health departments, voluntary agencies, the State, and the medical profession can be developed into an efficient organization, to the mutual advantage of the public and the medical profession. This is one of the important problems in health work today as well as in medical public relations.

The Medical Society of the State of New York is working out this

problem by the use of the principles of conference and coöperation and relationships.

Doctors endorse mass preventive practice but they are dependent upon other organizations than their own for its administration. They distribute preventive measures to individuals—one doctor to one patient at a time. The health officer must organize and provide for publicity for mass or semi-mass service.

There is growing in the minds of the public a knowledge that disease can be prevented to an extent, if diagnosed early enough to attack it in its incipience.

Many health influences are attacking the health problems that have not been met. Times are changing, and the doctor is changing with them. He is changing from the curing of disease only to the inclusion of preventive practice. The change is slow but it is as fast as any scientific body would move.

National Advisory Health Council Appointed

MEMBERS of the National Advisory Health Council, created by act of Congress in April, 1930, as an advisory body to the National Institute of Health, were recently appointed as follows: Dr. Simon Flexner, director, Rockefeller Institute for Medical Research, New York; Dr. Mazzyck P. Ravenel, professor of medical bacteriology and preventive medicine, University of Missouri School of Medicine, Columbia; Dr. Milton J. Rosenau, Charles Wilder professor of preventive medicine and hygiene, Harvard University Medical School, Boston; Dr. William H. Welch, Johns Hopkins University, Baltimore; Dr. Waller S. Leathers, dean and professor of preventive medicine and public health, Vanderbilt University, Nashville; Dr. Haven Emerson, professor of public health administration, Columbia University College of Physicians and Surgeons, New York; Dr. Samuel C. Lind, head of the department of chemistry, University of Minnesota; Dr. William H. Howell, director and professor of physiology, Johns Hopkins School of Hygiene, Baltimore; Dr. C.-E. A. Winslow, professor of public health, Yale University, and Dr. Alfred Stengel, professor of medicine, University of Pennsylvania School of Medicine, Philadelphia.

DROUGHT AND MALNUTRITION

IN spite of the fact that the newspapers have kept the country informed as to the drought of the summer of 1930, and the continued deficiency in rainfall during the present winter, there still seems to be a lack of appreciation of the matter, especially so far as the consequences are concerned.

Some 21 states have been affected more or less seriously, many of them having already suffered losses which cannot be made up until the crops of 1931 are harvested, even supposing the conditions will be favorable from this time on. In a number of states the fields of alfalfa and winter grain have either been injured or seriously threatened by the lack of moisture, and there is even danger of the death of trees. Only abundant precipitation in the near future can save these areas in the matter of crops and food.

From the standpoint of the readers of this *Journal*, the influence of conditions on the health of the inhabitants, particularly children, is the chief point of interest. At least 2 state health officers and the Surgeon General of the U. S. Public Health Service, have given testimony concerning medical conditions in the drought-stricken areas and the suffering which has resulted from a lack of medical attention and supplies, for which a prompt appropriation of 3 million dollars has been asked, to be expended by the Service. There is evident already undernourishment of children, and the menace of typhoid fever seems to be greater than for a number of years. In many areas the farmers

have not water either for their stock or for themselves. Water is being hauled from runs, creeks and springs to fill depleted cisterns and wells. Since the majority of these sources are not protected, the danger is evident. The demand for antityphoid vaccine as reported by manufacturing houses and by state laboratories has been much larger than usual, and county health officers are advising its wider use.

In some parts of the country, notably Arkansas, it is stated that the incidence of pellagra has increased. It will be well to remember that the late Dr. Goldberger pointed out the prevalence of the M. M. M. diet (meat (pork), molasses and meal) in the farming sections of the South, to which he attributed the increase in pellagra after the Mississippi floods a few years ago. The condition is much the same now as then, though perhaps exaggerated. Matters have been made worse by the lack of food for animals, and there is a practical certainty of a depletion of the already deficient milk supply. There is no doubt that the assisting agencies throughout the country will ship in milk and milk products to the full extent of their ability.

The health officers of the various states and communities are alive to the problems confronting them. The citizens to a great extent are unable to help themselves, through the loss of crops, the failures of banks, and the tying up of public funds. It is a time when not only competent advice, but assistance, is badly needed. Infants and children must be protected against undernourishment, the effects of which may persist throughout life.

PULMONARY TUBERCULOSIS OF BOVINE ORIGIN

ONE seldom now sees discussions of bovine tuberculosis in relation to human health, and the newer generation of health officers and public health workers has apparently forgotten, or never heard of, the bitter controversy which raged over the matter of human susceptibility to the bovine tubercle bacillus. All of them advocate the pasteurization of milk, but such things as undulant fever seem to be more prominent in their minds today than the danger of bovine tuberculosis. As a matter of fact, bovine tuberculosis in human beings seems to have greatly decreased, though we have few statistics based on its incidence before and after pasteurization. Where these figures are obtainable, they are in favor of pasteurization. It is perhaps superfluous to add that the tuberculin testing of milch cows is widely practised and many of our cities have ordinances requiring it.

Some of us can remember Koch's last stand on the question when the English and German Commissions had both reported that tubercu-

losis in cattle was a fairly frequent source of the disease in human beings, especially young children. At the Conference in Camera, which left a very bad taste in the mouths of many scientific men, Koch's final refuge was the statement that it had never been demonstrated as the cause of pulmonary tuberculosis, and when he was confronted with the statement that bovine organisms had been found in human sputum, he insisted that it must be shown that the patient had not eaten butter or any other food which might have contained the germ.

Certain English authors have shown a remarkable tenacity in pursuing this line of work, and we now have a report¹ from one of the most prominent English bacteriologists which proves conclusively that the bovine bacillus can and does cause pulmonary tuberculosis.

In England, 3 of 327 patients suffering from phthisis (slightly over 1 per cent) expectorated only bacilli of the bovine type. In Scotland, 18 of 468 (approximately 4.5 per cent) have been found, 17 of whom gave only the bovine organism, while 1 gave both human and bovine. Outside of these 2 countries, 926 examinations of sputum have been reported, all of which showed the human organism.

A majority of the cases showing the bovine type of organism gave clinical histories which indicated the alimentary tract as the portal of entry. Eleven patients have died, and on 2 autopsies were made, in each of which cavity formation was found, and pure cultures of the bovine organism obtained from the lung and other lesions, proving that the organisms found in the sputum had their origin in the lung disease. Autopsies on 4 cases of generalized tuberculosis with cavity formation due to the bovine organism are quoted, the anatomical evidence in 4 of the 6 post-mortems indicating the alimentary tract as the portal of entry. In 2 the evidence was inconclusive, but pointed to the alimentary tract rather than to the respiratory. In no case was there a family history of tuberculosis, nor any evidence that the disease had been contracted from a previous case, so for the present we can say that the cow is the only source of bovine infection in human beings. Other cases of fatal generalized tuberculosis in children due to the bovine organism are reported in which the anatomical evidence pointed definitely to the respiratory tract as the portal of entrance.

From the above, it can be stated positively that while rare, pulmonary tuberculosis, or ordinary consumption, may be due to the tubercle bacillus of bovine origin, and like other forms due to this organism, in the great majority the infection enters through the intestinal tract.

The facts recited furnish one more strong argument for the pas-

teurization of all market milk, in addition to the commendatory efforts which are being made to eradicate tuberculosis from dairy herds.

Koch's stand in the matter was the one great blunder of a remarkable scientific career. One should not forget what Abram Jacobi said on the occasion: "It is of more importance to save the lives of babies than to protect the reputation of one great scientist."

THE LUBECK DISASTER

WHILE it is probable that the true explanation of the Lübeck disaster will never be entirely known, the report from the German Federal Bureau of Health is of interest. The work was done by Professor Lange, and concurred in by Professor Neufeld, and Dr. Kirchner, of Hamburg. In the material which was available for study, were some remnants of the vaccine material which had been used, and a culture isolated from one of the infants who died of tuberculosis. From one of the vaccines, a virulent culture was obtained, while the growth from the other corresponded to BCG vaccine. The culture isolated from the dead child was apparently identical with strain H 29 of the Robert Koch Institute. The indications that the latter was used for inoculation is borne out by the fact that during part of the vaccination period there were many deaths, and at other times, very few, and not many severe illnesses. The explanation of reversion of type given by Petroff, of Saranac Lake, and Watson, of Canada, is regarded with skepticism.

The conclusion is that the accident in Lübeck was not due to the Calmette procedure as such, nor to BCG. It is regarded as "entirely probable" that there was a mixing of the virulent culture with the vaccine, through some error in handling.

The Federal Health Council holds the opinion that the whole question is so unsettled that general immunization of human beings, particularly when living bacilli are used, is for the present, ill-advised. In view of the Lübeck affair, it considers that the legal requirements regarding preparation, distribution and use of vaccines of all kinds, must be extended and insisted upon.

ASSOCIATION NEWS

CHARLES J. HASTINGS

IN the death of Dr. Charles J. Hastings on January 17, not only Canada, but the world has lost one of its outstanding teachers and practitioners of public health.

He joined our Association in 1911, became a Fellow in 1922, and was elected to Honorary Fellowship in 1926. He was the 46th President of the Association, having served in 1918.

Few members of our Association have endeared themselves to the membership as did Dr. Hastings. A hard worker and deeply interested in the affairs of the Association, he was always ready for any task, however difficult, and took prominent part in one of our reorganizations made necessary by the great growth in membership and the addition of sections along various lines. He was a fluent speaker with a wide range of knowledge, which was always at the disposal of the Association. For several years past he has been failing in

CHARLES J. HASTINGS, M.D.

health and has spent a number of his winters in Florida.

While mourning the loss to our Association, we extend to his family and associates our deepest sympathy.

WESTERN BRANCH A. P. H. A. MEETING IN SEATTLE

MAY 28 to 30, 1931, have been chosen as the dates for the Western Branch Meeting in Seattle, Wash. E. T. Hanley, City Health Officer of Seattle, is Chairman of the Committee

on Local Arrangements. The Olympic Hotel will be official headquarters. A list of hotels and rates will be furnished by the local committee to Western Branch members.

NEW MEMBERS

Health Officers Section

PUBLIC HEALTH ADMINISTRATION

HENRY F. VAUGHAN, D. P. H.

MEASLES CONVALESCENT SERUM

W. W. BAUER, M. D., F. A. P. H. A.

Commissioner of Health, Racine, Wis.

THE value of measles convalescent serum in prophylaxis and treatment of measles is firmly established and recognized by physicians and public health workers alike.

At the same time this valuable agent, at least in the smaller communities, has not been used to the extent which is desirable. This is due largely to the difficulties inherent in procurement and preparation of the serum to make it available at the time and in the place where it is most needed. There are two major factors which have created the present difficulty. One of these is a characteristic of measles epidemics, namely their periodicity. The second lies in the perishable nature of measles convalescent serum, a quality which it shares with all biological products.

Measles epidemics, as is well known to health administrators, occur at intervals of from 24 to 30 months. During each epidemic, it is possible to secure donors and to prepare convalescent serum from their blood. These donors are most numerous and most readily available at the height of the epidemic, whereas the most profitable use of the immune serum would be during the early stages of the outbreak. It is clear that measles convalescent serum gathered and prepared by any given community can under ordinary conditions be made available only when the time for its usefulness has largely gone by.

The perishable nature of the serum

makes any given batch of the product virtually useless after 6 months, or at least so reduced in potency that larger doses must be used, and even these do not give the desired assurance of successful prophylaxis or treatment. It is probable that any serum carried over from one epidemic to the next would be entirely without value.

These administrative disadvantages might be overcome by inter-community cooperation. Measles epidemics occur with fairly regular and predictable periodicity, but the cycle is not the same in all communities. There are cities which in 1931 are looking forward with apprehension to "a measles year." These communities know that lives will be sacrificed to this disease which might have been saved by prophylactic or therapeutic use of measles convalescent serum. In many instances, they will have no serum available, or only small amounts comparatively late in the course of the epidemic. If these communities could draw upon a common supply to which in turn they would contribute such quantity of serum as they might be able to procure, there would be a better chance all around of fighting the life loss from measles.

A cooperative plan for distribution of measles serum is therefore proposed and offered to health officers for their discussion and constructive criticism. The points outlined below are intended as a basis for discussion and not with any thought that they constitute a fully con-

sidered and workable plan. That there will be difficulties in its administration should be anticipated. Perhaps it will not work at all, and yet it seems to be worth consideration.

Briefly, the plan might be something like this:

1. A certain number of cities of approximately equal size might enter into a coöperative agreement which would stipulate that the health department in each city would locally procure all the measles convalescent serum possible.

2. All serum procured would be delivered to a central distributing point to be determined, and each city would be credited with the number of finished doses of convalescent serum manufactured from the blood delivered by that city.

3. Each participating city would, in turn, be privileged to withdraw, at the time of its greatest need, a number of doses equal to its credit and such additional number as might be available without working a hardship upon other participating communities.

4. The central distributing point would probably have to be a commercial antitoxin laboratory which would necessarily be a party

to the agreement. Such a laboratory would prepare the serum from blood received, keep a record of credits and debits for each participating community and the charges for this service could be distributed *pro rata* among the cities in proportion to the amount of finished product withdrawn.

As stated above, there will be difficulties of administration and it is entirely possible that the whole plan is not workable. On the other hand, if successful, a coöperative plan such as might grow out of discussion of the outline presented would, if practicable, greatly increase the availability of measles convalescent serum at the time and in the place where the greatest need exists and would greatly reduce the existing waste of this valuable material which now goes on because of the conditions outlined.

Pooled serum has already been considered in connection with poliomyelitis. The greater prevalence of measles, in comparison with poliomyelitis, seems to argue greater possibilities for the success of a measles serum pool.

LABORATORY

JOHN F. NORTON, PH. D.

AN UNUSUAL CASE OF CANINE RABIES

A. S. SCHLINGMAN, D. V. M.

Research Laboratories, Parke, Davis and Company, Detroit, Mich.

ON account of the 10-day observation period usually required for dogs suspected of being rabid which have bitten persons, the following case is of interest.

An adult male dog of mixed breed with no history of exposure to rabies was recently brought to my attention. This animal showed a tendency to conceal himself when an opportunity was afforded, and to bite when attempts were made to remove him. Inasmuch as these symptoms suggested the possibility of rabies infection, he was placed in separate quarters for further observation. No unusual symptoms were noted during the next 3 days other than a lack of appetite and a tendency to bark at anyone approaching the cage in which he was confined. On occasions attempts were made to bite objects thrust into the cage. There was also marked constipation.

During the next week the appetite and all body functions seemed normal and on the 10th day, the dog seemed only what would be termed a "cross dog." Nothing unusual was noted until the 15th day when there was again a lack of appetite and the development of slight nervous symptoms. There was also noted a tendency to chew the wires of the cage. This continued during the next day when it was seen that several of the incisor teeth in the mandible were broken off and that the gums and the mucous membrane of the lower lip were badly lacerated and swollen. No drool-

ing of saliva was seen on this or any other day during the dog's confinement.

On the 17th day the nervous symptoms had disappeared. The animal lay quiet most of the time but would rise when called. Next morning (the 18th day of observation) the dog was found dead. There was no evidence of convulsions which are usually seen prior to death from rabies.

Autopsy showed nothing unusual except a slight congestion of the internal organs. No foreign bodies were found in the gastrointestinal tract.

A diagnosis of rabies was made when Negri bodies were seen in smears made from the hippocampus major. To confirm this diagnosis, a portion of this part of the brain was ground in physiological saline solution and 0.5 c.c. of the suspension injected subdurally into 2 rabbits. One became paralyzed on the 14th day after injection and died 1 day later. The other remained normal for 12 days when beginning paralysis was seen, which was complete about 30 hours later. Death took place on the 14th day after injection.

Negri bodies were seen in smears made from the hippocampus major of each of these rabbits.

This case is reported because of the apparent lack of typical symptoms and also because it is evident that there may be cases in which the usual 10-day quarantine would not be sufficient to determine with certainty that a suspected dog was free from rabies infection.

A DEVICE FOR ASEPTIC DISTRIBUTION OF CULTURE MEDIA

W. L. MALLMANN

Department of Bacteriology, Michigan State College, Ann Arbor, Mich.

A NUMBER of devices for aseptic filling of test tubes with media have been perfected, hence the writer is somewhat hesitant in presenting another. However, the device herein described, although not totally new, is so much more convenient than those at present available, that its presentation seems justified.

The usual filling device consists of a covered funnel to which is attached a rubber tubing with a tapered glass tube tip, shielded by an inverted glass cone to prevent contamination reaching the glass tip or entering the tube during the process of filling. The funnel may be replaced by an inverted flask or bottle with appropriate fittings.

The glass shield device has never been a satisfactory arrangement due to difficulties of sterilization and breaking. The writer has substituted a metal apparatus as illustrated in the drawing (Figure I). In this simple apparatus, the tapered tip and shield are made in one unit. The device is made of copper, plated with nickel or chromium.

FIGURE I (actual size)

(Jr. article No. 57 (n.s.) from the Mich Agr. Exper. Sta.)

VITAL STATISTICS

LOUIS I. DUBLIN, PH. D.

Infant Mortality Decreased in 1929—The U. S. Department of Commerce recently reported that the infant mortality rate showed a marked decrease in 1929 as compared with 1915. The rate of 68 per 1,000 was the second lowest since the establishment of the birth registration area in 1915.

For the sixth consecutive year, Oregon led the states with the lowest infant mortality rate (48), and 11 states reached their lowest rates since 1915. These were Minnesota 51, Arkansas 58, New Jersey 60, Illinois 61, Massachusetts 62, Florida 65, Michigan 66, New Hampshire 68, Louisiana 74, Georgia 76, and South Carolina 91. Two states, Iowa and Maryland, maintained their lowest rates, attained in 1928.

With the exception of Colorado, Maine and Wyoming, the high infant mortality rates in 21 states were due to the high infant mortality among the negro population, especially in rural districts. The year 1929 saw not only the second lowest infant death rate since 1915, but also the lowest birth rate, which was 18.9. Oregon, besides leading the states with the lowest infant mortality rate, had the lowest birth rate (14.1) of any state during that year.—*J. A. M. A.*, 95: 1843 (Dec. 13), 1930.

Vital Statistics for London, England, 1929—The population of the County of London in the middle of 1929 is estimated by the Registrar-General to have been 4,430,000, including 12,100 non-civilians. This is a decrease of 37,700 of the civilian population since the middle of 1928. There were 70,089 births, equivalent to a birth rate of 15.8

per 1,000 as against 16.2 in 1928. This is the lowest birth rate ever recorded in London. The City of London has the lowest birth rate, 7.7.

There were 62,889 deaths, representing a death rate of 14.2 per 1,000 compared with 12.1 in 1928. This increase was due to the severe influenza epidemic and the epidemic prevalence of whooping cough which was mainly responsible for the rise of the infant mortality rate from 67 in 1928 to 71 in 1929. For the county as a whole, the death rate from whooping cough was 0.26 per 1,000 of the civil population.

The mild type of smallpox which invaded London during 1928 became established in many parts of the metropolitan area during 1929; no fewer than 1,908 cases were reported. The notified cases of diphtheria numbered 11,788 in the registration year, an attack rate of 2.7 per 1,000. The number of diphtheria deaths was 350 as compared with 399 in 1928, giving a case mortality rate for 1929 of 3 per cent.

A further diminution in the incidence of enteric fever was recorded; 351 notifications were received during the registration year as compared with 580 in 1928. The deaths in the calendar year numbered 45 as against 51 in 1928.

Fatal street accidents continued to increase in number, the total being 814 in 1929 as against 747 in the registration year 1928.—Report for 1929. *Brit. M. J.*, 2: 965-966 (Dec. 6), 1930.

Vital Statistics for Northern Ireland—During the quarter ended September 30, 6,513 births were registered in the 27 superintendents registrar dis-

districts in Northern Ireland. This number represents an annual birth rate of 20.9 per 1,000 of the estimated population. The equivalent figure for England and Wales is 16.6, and for Scotland 18.7. The rate in Northern Ireland is 0.2 above the rate for the corresponding period of 1929, and 1.8 below the average rate for the third quarters of the ten years 1920-1929.

There were 3,486 deaths registered during the quarter, or an annual rate of 11.2 per 1,000, being 0.2 above the rate for the third quarter of 1929 and 1.2 below the average rate for the third quarters of the 10 years 1920-1929. The urban mortality from the principal epidemic diseases recorded during the quarter was equivalent to an annual rate of 0.5 per 1,000 population. The death rate from these diseases for the remainder of Northern Ireland was 0.2.

Deaths from cancer numbered 330 or an annual rate of 1.06 per 1,000 compared with an average rate of 1.09 for the third quarters of the previous 5 years. The number of deaths of infants under 1 year of age was 34.9 or 10 per cent of the total number of deaths registered.—*Brit. M. J.*, 2: 976 (Dec. 6), 1930.

Annual Report of Surgeon General of Army, 1929—The general health of the army was satisfactory according to the report. The admission rate per 1,000 from diseases decreased from 586.53 for 1928 to 526.43 in 1929. With the exception of the rates for the years 1922 and 1925, the rate for 1929 was the lowest on record for the army. There was a slight decrease in nearly all classes of diseases, but the respiratory group, including influenza, was responsible for the greatest decline, as it was the most important cause of the increase in 1928. The death rate per 1,000 from all causes was 4.34, as compared with 4.10 in 1928. The increase

was due to a greater number of deaths from external causes. Although the rate from diseases decreased slightly for the year it was, with the exception of that for 1928 and 1927, higher than any other year since 1920, partly on account of the greater number of deaths from tuberculosis during the past two years as the result of the policy of holding enlisted men in the service for a longer period before discharge on certificate of disability than formerly.

The leading causes of retirement among officers were tuberculosis and chronic myocarditis, and among enlisted men, dementia praecox. The leading causes of noneffectiveness were gonorrhea, tuberculosis, syphilis, bronchitis, and injuries resulting from athletic exercises. The annual admission rate for the total male military personnel for venereal diseases was 48.33 per 1,000, which was 0.15 per 1,000 higher than it was in 1928; with this exception, the current rate is the lowest on record for the army. The total number of military personnel treated in hospitals and dispensaries during the year was 88,657, and the average number hospitalized daily, 6,613. The cost of maintenance of the 6 larger hospitals in the United States, exclusive of new construction, was \$5.21 per patient-day, a decrease of \$0.05596 per patient-day for the year.—*J. A. M. A.*, 96: 202 (Jan. 17), 1931.

The Epidemiology of Tuberculosis of Negroes—Of 10 million colored people in this country, approximately 25,000 die every year from tuberculosis. The falling death rate gives hope for the future but scant comfort at present, and in certain localities the death rate has increased rather than fallen.

An analysis by Sydenstricker, of the tuberculosis mortality in 1925 in the death registration area of the United States shows that for colored people, the mortality from the disease in both

men and women reaches a maximum between the ages of 20 and 24, when it is 4 times that of white people. The fall in death rate, more abrupt in colored women than men, is continuous throughout the remainder of life. The total death rate, unlike that of white people, is somewhat less in colored men than in colored women.

Statistics of the Metropolitan Life Insurance Company from 18,500,000 white people and 2,500,000 negroes show that the average death rate per 100,000 from 1925 to 1927 was for the white race 68.9, for the colored 203, a ratio approximately of 1 to 3. Negro children are more seriously attacked than white children, the ratio of deaths for the two races between birth and 15 years of age being 1 to 9.2, but from 15 up to 25, 1 to 3.9. As compared with figures of 1911 and 1913, the death rate from tuberculosis has fallen rapidly for both races, but the percentage of decline is somewhat less in each age group for colored than for white. The high mortality peak among colored females occurs in early adult life; among colored males, though the highest peak is at the same time, there is a higher proportion of deaths in middle life, as in the case of white males.

Postmortem observations suggest that the American Negro escapes tuberculous infection during childhood more frequently than white people and that he more often suffers in adult life from rapidly fatal tuberculosis with the characteristics of the first infection of white children.—Eugene L. Opie, *Epidemiology of Tuberculosis of Negroes*, *Am. Rev. Tuberc.*, 22: 603–612 (Dec.), 1930.

Cycles in Influenza and Pneumonia—During the last 10 years there has been a clear-cut 3-year cycle in the death rate from influenza among the industrial policy holders of the Metropolitan Life Insurance Company. In

each of the years 1920, 1923, 1926, 1929 and in no other year of this period, the weekly death rate at the peak of the seasonal curve rose above 100 per 100,000 per annum. The individual waves of the cycles bear a marked resemblance to each other and the general form of the three waves in the whole cycle is characteristic. Invariably a wave of maximum height with death rates over 100 per 100,000 per annum for the worst week is followed by a markedly smaller wave in the next year and in turn by a somewhat larger wave which culminates in the third year in the maximum wave of the cycle.

The pneumonia curve is similar to the influenza curve but lacks some of its perfect regularity. The pneumonia curve reached its maxima in the same years as the influenza curve—1920, 1923, 1926 and 1929. But although in the 1921–1923 and 1927–1929 cycles there was an invariably increasing seasonal maximum from the first year of the cycle to the last, the first maximum was a little higher than the second in the 1924–1926 cycle.

The crest of the curve both for influenza and for pneumonia comes usually at about the 9th or 10th week of the year while the ascending limb of the wave usually starts toward the close of the preceding year. The duration of the wave is about the same for the two diseases but the range of fluctuations in the death rate is much greater in influenza than it is in pneumonia. During the entire period of 10 years the annual maximum in the death rate from pneumonia ranged from 126 per 100,000 in the 10th week of 1921 to 678 in the 7th week of 1920. The annual maximum of the death rate from influenza varied from 20 per 100,000 in the 11th week of 1921 to 441 per 100,000 in the 7th week of 1920.

The influenza epidemic of 1918 was somewhat abnormal in several respects—

it came more than one year later than might be expected from the 3-year cycle and fell at an unusual time of the year. All the crests of the waves in the series 1920-1930 fell in the winter and early spring months usually February or March. The epidemic of 1918, however, began suddenly in September and ran high during the rest of the year, subsiding in April or May of 1919.—*Stat. Bull., Met. Life Ins. Co.*, 11: 1-4 (Nov.), 1930 and 11: 3-5 (Dec.), 1930.

Chronic Rheumatism in Massachusetts—A survey made in 1929 in the state of Massachusetts reports rheumatism the greatest single cause of chronic illness, with duration of incapacity from rheumatism much longer than from any other disease. In Massachusetts at any one time, there are approximately 145,000 individuals suffering with rheumatism; 89,000 with heart disease; 56,000 with arteriosclerosis; 31,000 with nephritis; and 10,000 with cancer. Nearly 85 per cent of the cases of rheumatism are in individuals over 40 years of age.

The survey shows that of the rheumatism patients 67.9 per cent were either treating themselves or receiving no treatment. In the well-to-do group, the percentage of self treatment or none at all was 50 per cent; in the poor group 75 per cent. When questioned as to the reason for not employing a physician 46.1 per cent said that the doctor could not help them and only 12.5 per cent gave economic reasons. Only a small per cent (0.6) received hospital care and 0.9 per cent nursing care. About 1 per cent felt they needed nurses but were unable to employ them due to economic reasons.

The median age of rheumatism patients was 62.6 years and the median age at the onset of the disease 51 years. The average duration of rheumatism up

to the present time was 11.6 years, complete physical disability being present in 4.2 per cent of the cases, and partial disability in 30.4 per cent. Among the poor, the complete disability rate was significantly higher, being 7.1 per cent. The average duration of disability during the past year among those confined to bed was 2.3 months, and among those confined to the chair 4.5 months. The average duration of partial disability was 6.1 months.

About 12 per cent of the patients with rheumatism were living in homes entirely unsuited for their care. About 12.2 per cent of the wage earning rheumatic patients were completely disabled economically, and about 12.2 per cent partially disabled. During the last year, 46.5 per cent of these wage earners lost an average of 4.6 months from work.

At Robert Breck Hospital, Dr. Francis Hall reported that of the total number of cases, 95 per cent were helped, 66 per cent with good results and 29 per cent with partial results. In this country better hospitalization for difficult cases, and good diagnostic clinics, furnishing advice, would facilitate the care of rheumatism.—*New Eng. J. Med.*, 203: 1232-1233 (Dec. 18), 1930.

Undulant Fever in 1929-1930—Undulant fever, in its various forms, tends to take an increasingly important place among infectious diseases prevailing in countries with a temperate climate. In Malta from 1926 to 1929 the disease has increased from 602 cases to 1,288, and during the first 8 months of 1930, 1,084 cases were recorded. In Italy the number of cases has remained practically constant, with 959 cases in 1928 and 956 in 1929; in the two years previous, the cases numbered 1,085 in 1926 and 1,071 in 1927. An epidemic of 32 cases in Florence was attributed to the consumption of cheese made from

the milk of sheep heavily infected with epizootic abortion, which had also prevailed among cattle.

In France where it appears that undulant fever formerly had its origin chiefly in goats, from Mediterranean areas, and where the majority of human cases now originate in sheep, the number of cases has increased from 124 in 1928 to 155 in 1929, and 164 in the first 9 months of 1930. The rural cases are attributed to contact with animals affected with epizootic abortion or with manure contaminated by them, and the urban cases are attributed to the consumption of raw milk and fresh cheese from these animals.

In Northern Africa, the infection is stationary, and in Turkey the disease exists but figures are missing. Yugoslavia showed only one case in 1929; Greece 35 during the first 9 months of 1930; Southern Rhodesia 13 in 1926; 2 in the first 8 months of 1930.

The number of cases of undulant fever is growing in Denmark from 372 in 1928 to 503 in 1929, and in Sweden, cases are numerous, with 118 in 1929.

Germany showed 57 cases in May, 1929, of which 25 were recorded in Schleswig-Holstein, 10 at Kiel, and 7 at Hamburg. Three cases in Poland, 1 in Czechoslovakia, 1 in Hungary, 14 (most of which were of bovine origin) in England and Wales, 1 in Scotland and 2 in Northern Ireland were reported.

Since 1925, the cases of undulant fever reported in the United States have increased rapidly from 24 cases in 1925 to 1,505 in 1929, with the greatest number in Ohio, Iowa, Missouri, New York State and Kansas. Every state of the Union had cases of the infection in man.

It is difficult to establish accurately the fatality of the disease because of pathogenic properties of the germ and because of a lack of sufficient characteristic symptoms to make diagnosis and statistical record possible. In the United States the fatality was about 3 per cent. The influence of occupation is obvious, veterinary surgeons paying a particularly heavy toll to undulant fever.—*League of Nations. Monthly Epidemiological Report*, 9: 409–417 (Oct. 15), 1930.

PUBLIC HEALTH ENGINEERING

ARTHUR P. MILLER, C. E.

EMERGENCY SANITARY MEASURES FOLLOWING A FLOOD DISASTER *

PAUL S. FOX, C. E.

*Chief Division of Sanitary Engineering and Sanitation
New Mexico Bureau of Public Health,
Santa Fe, N. M.*

IT is assumed that this title refers to the floods which occurred on the Rio Grande in New Mexico in August and September, 1929.

Before going into detail on the relief work, it might be well to describe the flood.

On August 13, word was received late in the evening that San Acacia, San Marcial and other towns in the Rio Grande Valley were flooded. The writer secured a supply of chloride of lime and left immediately for the flooded area. The small village of San Acacia had been covered with from 2 to 3 ft. of water. The residents had had only a few minutes warning and as a result they were able to save practically none of their belongings. The angry waters of the Rio Grande had backed up behind a highway bridge just above the village; when the bridge failed there was a rush of water which was sufficient to overtop the dikes and it was only a matter of a few minutes before the village was inundated.

The area affected was a strip of river valley varying from 2 to 5 miles in width and about 50 miles long. A large portion of this valley land was under

cultivation. All told, about 350 families were seriously affected by the flood. The devastation was tremendous. Adobe houses crumbled like lumps of sugar in hot coffee. Harvested crops were carried away by the swift current. Corn fields were flattened. New channels of the river selected choice farms for their new courses. Irrigation ditches and diversion works were demolished. Drain ditches were filled.

On September 23, another flood of greater proportions came down the Rio Grande. Areas left untouched by the first flood were completely wiped off the map. What was left in San Acacia was carried away and the main channel of the river cut through the side of the village. The entire area was covered with from 2 to 5 ft. of sand and silt. Railroad service was paralyzed as approximately 50 miles of track was damaged, about 5 miles completely gone and two bridges seriously damaged. Highway transportation was demoralized on account of bridges being washed out and grades being flooded or badly washed. In the first flood, San Marcial suffered only from surface runoff which was unable to get into the swollen river; however, in the second flood, the dikes gave away and the river came right through the town. River sand and silt was deposited to a depth of about 5 ft.

* Read before the Public Health Engineering Section of the American Public Health Association at the Fifty-ninth Annual Meeting at Fort Worth, Tex., October 28, 1930.

on the main street. In places one can walk on the sand and step up on the roofs of one-story houses.

In the second flood, from 12 to 48 hours warning was received that the high water was coming down the river, and all residents had ample time to move to higher ground. As a result no lives were lost and a large proportion of personal belongings was saved.

A passenger train carrying 70 passengers and crew was marooned between two washouts. Within one hour after the passengers were removed, the site was under 5 feet of water. The crew, however, stuck to their posts and it was 3 days before they were rescued.

Sanitary measures employed were as follows:

1. Protection of water supplies
2. Disposal of sewage
3. Typhoid immunization
4. Provision and inspection of food supplies
5. Assistance to the National Red Cross in rehabilitation
6. Hospitalization of the sick

In the flooded area, only one water system was affected. This was the Santa Fe Railroad supply at San Marcial. Approximately all of the residents obtained their drinking water from this supply. The source was a large dug well. Flood waters covered the ground surrounding the well but did not overtop the curb. Inspection of the masonry wall gave no evidence of flood water gaining entrance to the well at any point; however, as a precautionary measure, the well was dosed with 1 lb. of chloride of lime daily about one hour before the pump was started. Later bacterial examinations demonstrated that the untreated water was safe.

As in most rural communities, other sources of water were dug, driven and drilled wells. All dug wells in the area were inspected, cleaned where necessary, and dosed with chloride of lime. The amount of hypochlorite used varied with

the amount of water in the well, but at least 6 oz. were used. Driven wells were from 25 to 30 ft. deep and the ground water at this depth was not affected.

Even the worst disasters offer some amusing incident. This was no different. This particular well was not in the flooded area, but it had been filled with surface water following a severe rain. None of the family was at home, but one of the relatives was present when the writer came along. Explanation was made regarding the danger from the well water, and the well was "shot" with a liberal dose of lime. Instructions were left to the effect that if after a few hours the water tasted too bad, a large amount of the water in the well could be pumped out and gain the advantage of dilution with ground water. A few days later the writer was told that his method of sterilizing wells was no good, and that the best thing in the world to clean up a well was a quart of milk. The owner upon coming home found the water in his well rather tasty, so he proceeded to pump out the water and clean the well. He found an empty milk bottle in the bottom. The relative, hearing of the incident, recalled seeing me pour a white liquid into the well, and since there was a milk bottle in the well they concluded I must have poured in milk. The owner said the water in the well was "sweeter" than it had ever been before. Perhaps the cleaning was useful as well as the "milk."

In the refugee camps in the foot-hills, water from deep drilled wells was available. However, with several families living in each house, and many families living in tents supplied by the Red Cross, sanitary conditions were not the best. Toilet facilities were hastily provided where they were not already available, and all toilets were dosed daily with chloride of lime. The

amount of lime used daily may be questionable as to its sterilizing value, but it was certainly of value as a deodorant and fly repellent.

As soon after the first flood as vaccine could be procured, all members of the medical profession in the flooded area were pressed into service, and typhoid immunization was offered free of charge. Following the second flood, the vaccine was again offered. Approximately 1,800 persons received the initial dose of serum, and about 60 per cent of these received the three injections.

One case of typhoid was in San Marcial before the flood. It was necessary to place this case in the hospital. The father of this patient refused vaccination, and he later contracted the disease and died in the hospital. Four cases of typhoid fever developed in the flooded area, and they were all among un-vaccinated persons that had refused to be protected.

Hospitalization and funeral expenses were borne jointly by the Red Cross and the State Bureau of Public Health.

Following the second flood, all stores in San Marcial were in ruins. Some warning of the high water had been re-

ceived, and the storekeepers had been able to transfer some of their stocks to higher ground, but these were all consumed within 24 hours. The Red Cross brought in food supplies by truck and established a commissary where 1,000 people were supplied with food for several days. After transportation facilities had been repaired, and all families investigated by the State Bureau of Child Welfare, the Red Cross provided food only to those in need.

After the major preventive work had been completed, the writer was loaned to the Red Cross to assist in rehabilitation work.

In closing, it is desired to give a few words of praise where praise is due.

The Division officials of the Santa Fe Railroad, in spite of their troubles, were never too busy to give all assistance possible. The American Red Cross cannot be praised too highly for their prompt assistance in this matter. The State Highway Department, Bureaus of Child Welfare and Public Health voluntarily placed their representatives under the supervision of the Red Cross Director, and close coördination of all relief work was maintained at all times.

INDUSTRIAL HYGIENE

EMERY R. HAYHURST, M. D., PH. D., AND LEONARD GREENBURG,
M. D., PH. D.

Abnormal Mental States Among Industrial Workers—This highly mechanized age calls upon men to make tremendous adjustments and the machine does not recognize that a man has a soul, a self, an "I." Because of this, man will probably never be successful as a tool. Modern industry therefore tends to create neurotic problems.

Those who show abnormalities of self we have labeled "cranks," "trouble-makers," "nuts," "damn fools," etc. They are also of greatest concern to society. Not insane, they could be made of less concern to society if business or industry could assist more in their adjustment.

The "paranoid personality," or the one who is never quite ready to face fairly and squarely his own shortcomings, stands in about the same position in industry as the proverbial monkey wrench thrown into a machine. We psychiatrists believe that much can be done for such individuals. Occasionally a person with true paranoia gets into a responsible position in industry and he sometimes convinces others that his object of accusations is insane rather than himself. He is often a great potential danger.

A serious injury leaves one of two types—he who immediately sets about to adjust himself to the new conditions which must prevail, and he who refuses to be consoled and to attempt a reorganization of his economic life. In regard to the feeble-minded, and the epileptic, the former is usually rather easily adjusted as he is perfectly willing to furnish the eyes, ears, hands, and feet

for some machine. As to the latter, a job analysis should be made to see where he may fit in.

Industry, in trying to direct each worker into the thing he can do best, must recognize that society is made up of individuals of all stages of mental and physical health, and that grievances are pretty largely matters for psychiatric analysis as well as for the recognition of factual relationships.—Emerson North, M.D. Abstr. of paper presented before the Industrial Hygiene Section of the A. P. H. A., Fort Worth, Tex., October 27, 1930. E. R. H.

Findings After 7 Years' Experience of Compulsory Examination of the Eyes of Employees—At the request of the Eyesight Conservation Council, the Eastman Kodak Company, through its Medical Department, made a special survey to determine the findings of ocular conditions after 7 years' experience, where each year about 5,000 applicants, averaging 21 years of age, were examined.

It was found that about 13 per cent of the applicants needed glasses; 40 per cent of those already wearing glasses needed to be refitted; and a small percentage had diseased conditions needing medical attention of which conditions they were quite unaware. A number of the applicants had never suffered from headache, eye strain, or other symptoms, which indicates that a check-up now and then is a beneficial procedure.

The company in 1914 inaugurated complete physical examinations of all applicants for positions, a procedure

which is still required. Ocular examinations are necessarily more precise for working in some departments than in others. In the recent study, the applicants considered were almost evenly divided as to sex, there being 276 men and 224 women. As to age, 462 were under 40 years of age and 38 were over 40. Of the 462 under 40, only 78, or 17 per cent, had poor vision; of the 38 over 40, 13, or 34 per cent, had poor vision. This indicates that age is a decisive factor. In 1922, out of 3,280 employees, 1,231, or 37.5 per cent, were found to have defective vision (including those wearing glasses as well as those not wearing glasses). These were employees of Kodak Office, Camera Works, and Hawk Eye Works. The average age of the group was considerably higher than that of applicants for employment.

In a group of 435 older employees, 310, or 71.3 per cent, were found to have defective vision.

A record of symptoms among these employees showed that in spite of the fact that 124 of 259 persons who had never worn glasses made no complaints of headaches or eyestrain, the other 135 complained of such symptoms, and 93 needed glasses. Reexaminations are more likely to result in a prescription for glasses than an initial examination. Occasionally some actual pathology is discovered through these ocular examinations.

To date, no extended study has been made of results of improved vision on production and efficiency. Individual cases have come to attention where improvement has been marked, while relief from headache and eyestrain has a beneficial effect on general condition and efficiency.

Less extended statistics (regarding eye examinations) are also given for Montgomery Ward & Co., Oakland, Calif., The Chicago Northwestern Railroad, and others by the U. S. Public

Health Service, as well as The Metropolitan Life Insurance Co., and the Life Extension Institute.—Mimeograph report J. Walter Thompson Company, 420 Lexington Ave., New York, N. Y., Nov., 1930.
E. R. H.

Clinics and Clinics Procedure—

The first prophylactic clinic of the Consolidation Coal Company, Inc., was conducted in 1927. The advance work met with many objections and a few threats. After 400 home visits presenting the plan and objectives, at which time consent slips were left with parents to have their children protected against certain diseases and stating that they were privileged to go to any physician whom they might prefer at their own expense but that the company would pay for its employees, 186 children were immunized that year against diphtheria. In 1929, 572 children were so immunized with less than 100 home visits.

In February, 1928, when 2 cases of smallpox appeared in Harrison County, W. Va., a prophylactic clinic was in operation within 48 hours and with the help of the local press 3,024 persons were vaccinated, the County Health Department furnishing the vaccine.

In August, 1928, advantage was taken of the appearance of a typhoid case in one of the camps to proclaim immunization which was only fairly successful for the first treatment, but before the second treatment was due, 2 more cases developed, and this brought the attendance at the clinic to 100 per cent of all persons in the camp. No further developments and no deaths occurred.

In 1930, the second typhoid immunization campaign was put on when 1,765 completed vaccination for typhoid. Hence, the workers were realizing and appreciating the efforts to protect them.

In our experience in coal mining camps, advance work consists of home visits, talks in the schools and churches, and at games and social functions.

Proper publicity, necessary equipment, etc., are arranged through the mine office and company store.

In regard to prenatal clinics, it was found that they were not successful when the patients were asked to come to the office, but became successful when arrangements were made to conduct the work in the homes and a day set aside for this purpose each month has proved satisfactory. The doctors and the nurse make the rounds and each case receives routine or special care and instruction as indicated.

Preschool clinics in these camps have not proved a success thus far, so far as corrective work goes. Among other reasons is that the parents fail to see why children should be examined before starting to school when they are required to be examined soon after entering and add: "We never have the money to have them fixed up." (An accompanying table shows the number of clinics and the attendance in the company's camps for the years 1929 and 1930.) The type of clinics comprises prenatal, nose and throat, tuberculosis, venereal diseases, well baby, preschool, immunization, and others.—M. G. Frazer, R.N., *Special Report*, Consolidation Coal Company, Inc., Medical Department, Fairmont, W. Va. E. R. H.

Junior Wage Earners—In Ohio the Bing Law requires all children to remain in school until they are 16 years of age. Working permits may then be issued as follows: regular permits to boys and girls, 16 or 17 years of age who have completed at least the 7th grade of school and who can pass the physical examination; retarded permits to those of the same age who have been unable to complete the required 7th grade because of mental retardation; part-time permits to children 14 years of age and over who are still in school, and who desire to work before and after school hours or during vacation; con-

ditional permits to those of 16 or 17 years of age who have mental ability to complete the 7th grade, but who, through lack of educational opportunity, have failed to do so before they became 16 years old.

The Cleveland school system has just completed a notable study of 13,875 such permits granted for the year ending July 1, 1929, and represented by 10,790 first permits and 3,085 renewals. There were 8,263 boys and 5,612 girls given permits of one type or the other.

With the boys, it was found that 19.9 per cent went into the metal trades, 10.1 into the telegraph industry, and 6.2 into the electrical manufacturing and the retail food industry respectively, the balance into widely scattered industries. With the girls, it was found that 23.8 went into housework, 19.1 in department stores, 13.4 into clothing manufacturing, 6.0 into electrical manufacturing, and the balance were widely scattered.

Each time a boy or girl between the ages of 14 to 16 changes from one job to another a new work permit must be issued. Permits so issued during the school year average 1.3 per child, the rate being the same for boys and girls. Nearly 80 per cent of the regular work permits issued were granted to 16-year old boys and girls. Those of foreign parentage obtained almost half of all work permits issued.

Only 1 in 16 permits was issued to a retarded child, boys averaging a little higher than girls. Boys of German and Austrian parents averaged only half as many of this type of permits as the entire group of boys under consideration. Negro boys received 5.7 times the number of retarded permits for all groups, while the Negro girls received 8.5 times the girls' average. Italians ranked next with 1.7 times the average for boys and 2.7 times the average for girls.

The older boys work in metal factories in larger proportion than the

younger boys, who usually work for a telegraph company, a retail food concern, a department store, etc. More than one-half of the boys in the latter trades quit within 1 month, while the department stores and electrical manufacturers retain their boys for 6 months or longer.

Girls who are 14 or 15 years old work in the department stores' group in largest numbers. The second largest group do housework and the third largest group work in retail food establishments. Many of the girls employed by department stores quit in less than 1 month, although almost 50 per cent work more than 3 months. Almost three-fourths of all work permits issued to Negro girls were for housework. In view of this fact it is unfortunate that so many of these girls elect commercial and industrial courses during their school year. The percentage of white girls doing housework decreases with each grade of school completed, while the percentage of those who enter the employ of department stores increases with each grade of school completed.—C. W. Hall, *Educational Research Bull.*, Ohio State University, 18, 18: 2508-2511 (Dec.), 1930. E. R. H.

International Conference on Silicosis, Johannesburg, South Africa—The Conference was opened by H. W. Sampson, on August 13, 1930, who directed attention to the importance of the problem of silicosis, the compensation of nearly 1,000,000 pounds per year expended upon it in the Rand, and the value of an international effort to study methods of coping with it.

Dr. L. G. Irvine, Director of the Miners' Phthisis Bureau, having been elected as Chairman, the Conference proceeded to discuss the three questions submitted for its consideration: (1)

The medical aspects of silicosis; pathology and clinical phenomena of the disease; (2) preventive measures; and (3) compensation.

The Conference closed on August 27, and was able to reach agreement on a number of recommendations which will be published shortly.—*Industrial and Labour Information*, League of Nations, XXXV, 12: 364 (Sept. 22), 1930.

In connection with the above Dr. A. G. Cunningham of the Canadian Bureau of Industrial Hygiene who attended the Congress reports a summary in the January, 1931, issue (22, 1: 44-46) of the *Canadian Public Health Journal*. He dwells especially upon diagnosis in which the Conference recommended for general acceptance the classification of cases of silicosis developed and used in South Africa, viz., "First Stage," "Second Stage," and "Third Stage." The so-called "ante-primary" is the "first" compensable stage. The chief characteristics are given for each stage. Under prognosis the ante-primary case has a life expectancy of 13 years, while practically all cases ultimately progress, usually with the development of tuberculosis, to total disability. Compensation matters are also touched upon. E. R. H.

Compensation for Silicosis in Sweden—The Swedish Riksdag has adopted an amendment to its occupational disease act providing for compensation for silicosis. It is now accepted as having been fully investigated and is a typical occupational disease. The act will also cover other diseases of the lungs caused by stone dust, in addition to silicosis, and will come into force on January 1, 1931.—*Indust. & Labour Inf.*, League of Nations, XXXV, 12: 311-312 (Sept. 22), 1930.

FOOD, DRUGS AND NUTRITION

WALTER S. FRISBIE

Some Observations on the Behavior of Vitamin A in or from Primary Sources—This study was undertaken on food rich in vitamin A to determine the effect of storage on rancid fat soluble in vegetable oil and the effect of ultra-violet light. Dried ground spinach was stored in mason jars in diffused light and the potency tested on experimental animals.

At the beginning of the experiment, 20 mg. of the material was sufficient for weight gains. At the end of 6 months, 30 mg., and after 15 months, 100 mg. showed definite loss of vitamin A potency in storage during the period. The destruction of the vitamin during this period is estimated in the neighborhood of 70 per cent. Experiment work has shown the destruction of vitamin A by products found in rancid fats. Rancid butterfat was added to dried, powdered spinach and the finished sample contained 20 per cent of added fat. Parallel tests on those recorded for the storage experiment were made, making allowance for butterfat. Animals fed 30 mg. portions of the rancid fat alone made no growth.

At the beginning of the period, 34 mg. daily portions were sufficient, after 6 months, 0.036 mg., after 12 months, 0.063, and after 15 months 0.125 mg. The animals made practically the same gain the first 8 weeks on the fat-spinach mixture as was observed on the spinach supplement alone, indicating no rapid or marked destruction of the vitamin A in the rancid fat at this time.

To determine the solubility of vitamin A of plant tissue in oil, 3 products were used—tomatoes, carrots and broccoli. These were dried in an air oven

and triturated with peanut oil. The mass was filtered and the clear oil fed. Gains of experimental animals on the oil supplements indicated that the vitamin A of these 3 types of plant tissue is readily soluble in peanut oil.

In determining the effect of ultra-violet light, petroleum extracts of carrots were irradiated in quartz flasks at a distance of 12 inches from a mercury quartz lamp for from 3 to 5 hours. The extracts evaporated upon cornstarch were fed to rats in comparison with similar amounts of non-irradiated extracts. Rats on the non-irradiated extracts made good growth throughout the entire experimental period of 56 days. Those on irradiated supplements made no more gains than those on the vitamin A-free diet.—E. J. Quinn, J. G. Hartley, M. A. Derow, *J. Biol. Chem.*, 89: 657 (Dec.), 1930.

Evidence for the Presence of a Third Factor in the Vitamin B Complex of Yeast—Recent literature recognizes two very definite factors in vitamin B complex, but the reports on the third or vitamin B₃ are contradictory. This is described as thermolabile by 4 out of 5 recent investigators. The fifth reports this as thermostable. This principle is recognized as necessary for the normal growth of pigeons but as to rats evidence is contradictory.

In the present experiment, white rats were fed a basal diet deficient in all factors of vitamin B contained in yeast, supplemented by adding whole yeast and various fractions for different groups. The preparations employed were: an extract containing the thermolabile, antineuritic factor B₁, an extract

containing the thermostable factor B_2 , and the residue after extraction of these factors which is termed Fraction R.

Fractions B_1 and R were dried in air and B_2 concentrated with water so that each c.c. represented 4 gm. of the original yeast. The basal diet contained all of the vitamins except B complex. The controls on the basal diet showed definite symptoms of avitaminosis. Those on the whole yeast with other preparations were in excellent general condition and showed normal growth. The rats on the antineuritic Fraction B_1 supplement failed to grow but no polyneuritis developed. Those on the B_2 factor gained at first but later lost and in two cases developed polyneuritic symptoms. None of the animals showed the red, bleeding lesions of the eyelid as displayed in the group deficient in B_2 . Fraction R failed to promote growth. All of the rats developed eyelid lesions but no true polyneuritis.

The growth curves of the rats on the whole yeast extracts are better than any single group but not entirely normal. The fact that extraction of yeast is not equal to whole yeast may be explained by either the failure of the extraction to remove the water-soluble vitamin or that there is a water-insoluble growth factor. The authors favor the latter. The fact that this is not vitamin A nor D is demonstrated by the fact that the basal diet contains adequate amounts of butterfat and cod liver oil, while there is an optimum amount of salt mixture. Since the Fraction R is thermostable, it is regarded as similar to the factor described by Hunt. (*J. Biol. Chem.*, 79: 723, 1928), but differs from all other similar factors described.—Geo. Z. Williams and Robert C. Lewis, *J. Biol. Chem.*, 89: 275 (Nov.), 1930.

The Toxic Effects of Fish Liver Oils and the Action of Vitamin B—
Numerous instances are cited in the

literature on the toxic effects of fish liver oil, and in some instances constituted less than 2 per cent of the diet. In testing oils for vitamin A, symptoms closely resembling vitamin B deficiency were observed in experimental animals on large doses of cod liver oil and a basal diet of 10 per cent of yeast. Since there was a variation in the toxic effects of different oils, systematic experiments were undertaken to determine if this were due to variations in vitamin A and D. Two basal diets—one with 10 per cent yeast and the other with 18 per cent—were used.

The oil was fed in amounts up to 0.2 gm. per day. Two oils were used, one 5 times as potent in vitamin A as the other. With 0.207 gm. daily dose of oil, the animals after 3 to 4 weeks were apparently normal after which they exhibited vitamin D deficiency.

On an 18 per cent yeast ration vitamin A deficiency was observed at low levels, but normal rate of growth when fed 0.207 gm. The more potent sample showed normal growth for all levels of oils on both 10 per cent and 18 per cent yeast.

Cod liver oils of varying potency were compared with ratfish-liver oil less potent in vitamin A than the others. The ratfish-liver oil was taken with a 10 per cent yeast diet, although on 18 per cent yeast, normal growth was obtained.

To determine the relationship of vitamin D, rats were fed 0.05 gm. cod liver oil which would give good growth on the highest level on a 10 per cent yeast diet, and with added excess vitamin D as activated ergosterol. The animals showed normal growth on both 10 and 18 per cent yeast.

The vitamin D was only 1 to 4 times the amount received with the cod liver oil, compared to 10 to 100 times the dose showing deleterious effects. In addition to the neutral glycerides of cod liver oil, phospholipids and sterols, the

product contains various amines, isomylamine constituting one-third of the bases present.

It was found that small doses of isomylamine in amounts found in cod liver oil result in paralysis, convulsions and lack of growth and that this toxicity may be offset or prevented by adding yeast. The authors point to the fact that the quantitative determination of vitamin A in cod liver oil is influenced by the amount of yeast in the basal diet and that determinations of vitamin B are not comparable where cod liver oil is used to furnish A and D factors.—Earl R. Norris and Anna E. Church, *J. Biol. Chem.*, 89: 437 (Nov.), 1930.

A Study of the Japanese Persimmon Grown in Florida. I—Chemical Analysis—The production of the Japanese persimmon in Florida has been greatly stimulated since this fruit matures in late summer and early fall when there is little other fruit in that section of the country. A study was made to secure data on the chemical composition of the different varieties and on the vitamin content of one variety—the Tane Nashi. A description, as well as a table showing the composition, is given of each variety of the Japanese persimmon. Analyses for carbohydrate, moisture, ash, fiber, and protein were made on individual fruits. In its high carbohydrate content, the persimmon seems to be in the same group with fresh figs, fresh prunes, and bananas. Another characteristic is its low fiber content, it being so small in some varieties that it cannot be estimated with accuracy.—Jennie Tilt and Rebecca B. Hubbell.

II. The Vitamin B Complex—In the study for vitamin B the method of Sherman and Spohn was used to determine the amount of persimmon which must be added to a B-free diet in order to maintain animals over a period of 8

weeks. Albino rats, 28 days old, weighing 40 to 50 gm. were used. A basal diet of B-free casein 18 per cent, cornstarch 68 per cent, butterfat 8 per cent, Osborne & Mendel salt mixture 4 per cent, and cod liver oil 2 per cent was used.

The persimmon was fed at the following levels, 1.0, 1.5, 2.0, 2.5, 4.0, and 5.0 gm. daily. Tables give the average weight curves as a result of the experiments. There is very little variation in the average weight curves for the different levels indicating that the persimmon does not have sufficient vitamin B for maintenance, when the rest of the diet is adequate except for this factor. In all cases there was practically no increase in weight but a steady decline, and none of the animals lived through the entire experimental period of 8 weeks.—Jennie Tilt, Rebecca B. Hubbell and Lois Inman, *J. Home Econ.*, 22: 757 (Sept.), 1930.

The Nature of Dietary Deficiencies of Milk—It has been pointed out that milk is too poor in iron to meet the needs of the growing young and that the young are born with a store of iron to last through the suckling period. Numerous experiments have shown that when young growing rats are put on a milk diet alone, growth is arrested and anemia develops. Hart & Steenbock have shown that the addition of copper and iron to such a diet results in prompt relief of anemia (see abstract this *Journal*, 18: 1059, August, 1928).

The experiments reported in this paper show the reproductive behavior of rats on rations consisting chiefly of dried milk. Tables are given showing the percentage composition of the diets used and a summary of the reproductive histories of the animals. Of 38 diets in which milk powder was used, at 60–85 per cent level in combination with other substances, only 24 lived for production

of young. In only 4 cases were there 5th generations. The supplements used in these diets were cooked, dried beef liver, 4 and 5 per cent, yeast 5 per cent, and a combination of ferric citrate and copper sulphate.

Rats on milk supplemented with ferric citrate and copper showed normal growth and fertility for 6 generations. The authors point out that there is probably a quantitative relation of liver and milk more favorable to growth than that employed in their diets.—J. Ernestine Becker and E. V. McCollum, *Am. J. Hyg.*, 12: 503 (Sept.), 1930.

Viability of Lactobacillus Acidophilus and Lactobacillus Bulgaricus Cultures Stored at Various Temperatures—The writer conducted a number of experiments to ascertain the viability of *L. acidophilus* and *L. bulgaricus* strains when stored at different temperatures. One strain of *L. bulgaricus*, two stock strains, and one freshly isolated strain of *L. acidophilus* were used in the form of cultured milk for the purpose of these experiments. One commercial broth culture of *L. acidophilus*, as well as laboratory stock cultures of Lactobacilli were also included in similar studies.

The author states that milk cultures of *L. acidophilus* may be stored at refrigerator temperatures for several days without causing any marked reduction in the number of viable organisms.

Less reduction in numbers of *L. acidophilus* occurred at refrigerator temperature, 9° C. (48° F.) or even at 0° C. (32° F.), than occurred at 37° C. (99° F.).

Apparently there was little difference in viability between organisms in acidophilus milk kept several days at refrigerator temperature 9° C. (48° F.) and at 22° C. (72° F.).

From these results, the author is of the opinion that cultured milk could be held at the usual storage temperatures of 4.4° C. (40° F.) or below, for several days without greatly affecting the number of viable acidophilus organisms and controlling the palatability on the basis of decreased acid production. The various strains of *L. acidophilus* examined, all reacted similarly to the different storage temperatures. The strain of *L. bulgaricus* used also reacted in a similar manner. Results of one acidophilus commercial broth culture indicated that refrigerator storage was also preferable to storage at room temperatures for that product.

Laboratory stock cultures of *L. acidophilus*, whether old or recently isolated strains, remain viable when held in the refrigerator and transferred once in 4 to 6 weeks, or longer. In one instance, a sealed tube of a freshly isolated fecal strain stored at refrigerator temperatures for 1 year was viable when removed.—Luther A. Black, *J. Dairy Sci.*, 14: 59 (Jan.), 1931.

CHILD HYGIENE

RICHARD A. BOLT, M. D., DR. P. H.

NEONATAL MORTALITY

IN these columns last month it was suggested that inherent weakness of the developing embryo and fetus may account for no small part of the high fetal and neonatal mortality. Those of us vitally interested in child hygiene should keep abreast, therefore, of recent contributions to eugenics and racial hygiene. It is becoming increasingly evident that there is an enormous loss of life *in utero* and that this is intimately related to the morbidity and mortality of mothers and prospective mothers. Some years ago Ballantyne estimated that out of every 1,200 conceptions there eventuated 1,000 live births. At present it seems that Karl Pearson's estimate of 1,500 conceptions to every 1,000 live births is nearer the real situation. Testimony from leading obstetricians and gynecologists indicate that there has been an undoubted increase in abortions since the World War, especially induced abortions. These have contributed materially in keeping maternal mortality unduly high in this country.

Detailed studies of maternal mortality, conducted in a number of the states in coöperation with the U. S. Children's Bureau, have revealed abortion as a potent cause of maternal death. For example, in a study of the maternal mortality in Kentucky for the year 1927¹ it was found that 45 per cent of all puerperal deaths were due to septicemia, and of these more than two-fifths followed abortions, at least half of which had been induced. In a similar study of 1,627 deaths of women in Michigan from causes connected with child-birth² it was discovered that there were 465

deaths of which abortion was either the direct or indirect cause. This represented 28 per cent of the puerperal deaths for the 2½ years under consideration. In other localities from 25 to 35 per cent of the maternal deaths have been found to be connected with abortions, a large percentage of which were induced. While this condition involves more than the attention of the health authorities, a large share of responsibility must be placed upon their shoulders for a broader education as to the dangers of abortion, and more ample provisions for prenatal instruction and community obstetric service.

Clearly, most of these early deaths are not a part of a process of natural selection, but are due to the ignorance, carelessness, or thoughtlessness of the parents, especially the mother, or to the lack of judicious and skilled medical and nursing care at the time of confinement. It has been difficult to draw any exact conclusions in the past, due largely to the incompleteness or inaccuracy of statistics of fetal and neonatal deaths. The clinical aspects of the cases have not been sufficiently stressed in the birth and death certificates. Up to a few years ago complete autopsy findings of fetal and neonatal deaths were not available in any large number, and hence it was difficult, if not impossible, to assign to deaths their real causes. Considerable light has been thrown upon the causes of neonatal deaths by the Child Life Investigations of the Medical Research Council of Great Britain.³

The report of Dr. Cruickshank is very enlightening. He sets forth a de-

tailed description of the autopsy and serological findings of 800 neonatal deaths which were examined by him at the Glasgow Royal Maternity and Woman's Hospital. His findings merit close attention:

1. Of the 800 neonatal deaths (within 28 days of birth) 540, or 67.5 per cent, were classified as being due to asphyxia neonatorum, congenital atelectasis, prematurity or birth injury, that is, associated with delivery. Four hundred of these infants were premature and 140 full term.

2. In 238 cases, or 29.75 per cent, death was due to some infection acquired either before, during, or after delivery.

3. Death in 22 cases, or 2.75 per cent, was due to some developmental defect.

4. Seventy and six-tenth per cent of the total deaths occurred during the first week of life; 19.4 per cent during the second week; 7.3 per cent during the third week; and 2.7 per cent during the fourth week.

5. The presence of congenital syphilis was definitely established in less than 1 per cent of the whole number of cases. This is a smaller percentage than found in other series but can be accounted for by the fact that this series is dealing only with neonatal deaths and not with stillbirths among which syphilis is a cause of a much higher percentage, ranging from 10 to 15 per cent.

Dr. Cruickshank points out, further, that a large proportion of the neonatal deaths have causes which must be sought in the causes of stillbirths rather than in post-natal conditions. He offers the following suggestions to improve conditions:

The suggestions are made in a tentative way and with a full appreciation of the administrative and financial difficulties which their adoption would involve.

1. Increased efforts should be made to deal with preventable accidents and injuries incidental to delivery. This means that the antenatal supervision of the pregnant women must be encouraged and must be continued up to the time of delivery. . . . The public requires still further education as to the need for supervision—not merely for the detection of the toxemias of pregnancy, urinary infections and other medical complications of pregnancy, but in order that threatened obstetrical complications may be foreseen and treated in the most appropriate way.

2. It is not sufficient to urge upon the public the necessity for antenatal supervision during pregnancy. If such advice is to be followed then there must be increased facilities for antenatal examination and treatment, both at clinics and in hospitals. Further, there should be a much greater number of beds available for the indoor treatment of obstetrical cases.

3. No scheme for dealing with neonatal mortality would be complete which did not include some measure for the improvement of the education of medical students, graduates, and midwives.

The whole report would bear careful reading. The extensive list of references at the end permits one to follow the other investigations which have been made along the same line.

It is well recognized that the successful outcome of prenatal care depends largely upon early examination and observation by the physician, and regular systematic follow-up with careful instructions on the part of a trained public health nurse. The medical technics and nursing routines already have been thoroughly worked out and tested by experience in the field and hospital, and where these have been applied from early pregnancy until the successful termination of that event, a satisfactory outcome for both mother and child is reasonably expected. The greatest difficulty appears to be encountered in influencing prospective mothers to place themselves under competent medical and nursing supervision as early in pregnancy as possible. Why does this condition still exist and make it so difficult to carry out satisfactory prenatal care? The following seem to conspire to bring this about:

1. Lack of knowledge on the part of the parents, especially the pregnant mother, as to the supreme importance of systematic prenatal care begun early in pregnancy

2. Indifference on the part of the pregnant mother and the feeling that pregnancy is wholly a normal process and does not need attention until late in pregnancy

3. The feeling that the cost of obstetric service will be raised by prenatal care

4. The lack of adequate prenatal care to follow up the cases

5. Lack of encouragement on the part of the physician

None of these obstacles are insuperable and where good community co-operation between the health authorities and the nursing and medical professions has been brought about practically all of them have been overcome. There is no question in the minds of those who have had an opportunity to study the effects of an adequate prenatal care and obstetric service that maternal and early infant mortality can be greatly reduced.

Various methods have been tried to secure and hold the interest of prospective mothers in prenatal care and supervision. The logical place to begin such education is in the secondary schools as part of courses in child care and pre-parental education. The Mothercraft Movement and Little Mothers' Leagues created a great deal of interest 8 or 10 years ago and various modifications of these have existed in some of our schools. There needs to be a revival of such movements along modern educational lines. That this matter is still receiving serious attention on the part of some of our educators is seen from recent articles in the *Journal of Home Economics*.⁴

Miss Parsons sketches a practical course which has been developed in the Fordson High School at Dearborn, Mich. The following outline indicates the scope of the course and the subjects covered.

I. The girl herself

A. Attractiveness and personality

1. Environment

a. Home

b. Members of the family

2. Heredity

B. What a family is and does

1. Responsibilities of the family to the girl

2. Responsibilities of the girl to the family

3. Responsibilities to herself

a. Health: physical; mental; social friends, choosing a mate

b. Knowledge of life

c. Human development; adolescence

II. Child development

A. Pregnancy

1. Care (diet, elimination, rest, etc.)

2. Preparation of baby's clothing

B. Confinement

C. Infant care (physical, mental, social health; bathing, feeding, sleep, exercise, sunbaths)

D. Child care (physical, mental, social, emotional, and esthetic development as influenced by such matters as food, clothing, sleep, elimination, simple diseases, play, playmates, learning to talk and to walk, discipline, fear, anger, holding grudges, love, appreciation of nature, music, art, and literature)

This course is made very practical by demonstrations of bathing, feeding, etc., and the class is divided into groups which make a study of children at different ages and report their findings to the whole class. Round table discussion is promoted. The group reports are then brought together in a class notebook with newspaper and magazine articles collected by the girls. The community aspects are demonstrated by a visit to the Merrill-Palmer School.

If such courses were conducted by well qualified public health nurses on the staffs of our secondary schools and credit allowed for the courses, a sound basis for maternal and child hygiene might be laid.

PUBLIC HEALTH NURSING

EVA F. MACDOUGALL, R. N.*

Standards for Public Health Nurses in a City Board of Health—
The Detroit Board of Health has officially passed the following resolution defining educational standards for its nursing staff:

The public health nurse must have a fundamental education so that she can undertake successfully instruction of the general public in matters of public health as follows: prevention of illness; measures to be carried out to secure the alleviation of sickness; social service matters which involve proper hygiene in the home—this may involve such budgetary management of income that the nutritional requirements of the family may be adequate; child hygiene; applied psychology; a knowledge of welfare agencies which are available, together with the aid they can render; a sound theory and practice of rest, exercise, food raiment, cleanliness, and how inciting agents of disease are spread; laws, regulations, and procedures for preserving the public health.

All these activities impel the Board of Health to require a degree of intelligence and training for its public health nurses which is commensurate with the responsibilities involved. Therefore, be it

Resolved that, The standard of requirement for admission to the Nursing Division shall be: A college training or its equivalent. Until this standard can be attained, applicants must have at least graduated from an approved high school; graduated from a nurse's training school of an accredited general hospital, which has a daily average of not fewer than fifty patients. The training school of course must extend at least for a period of two and one-half years. Training for shorter periods will not be considered; some nursing experience; a nurse will not be given a permanent position until she has satisfactorily demonstrated her ability during a probationary period; excellent health, as indicated by physical examination made

by the department's Nurses Clinic; U. S. citizenship; registration to practise nursing in the State of Michigan; minimum age 23, maximum age 35, unless already trained in public health nursing, and possessing a record of accomplishment; postgraduate work in public health nursing, and an experience with a well organized agency which provides adequate supervision is desirable; credentials as to character, approved by the Department of Health.—

Congratulations, Detroit!—*Pub. Health Nurse*, XXIII, 1: 18 (Jan.), 1931.

Miss Hudson Leaves for the Orient—Nurses, and especially public health nurses, of this country and of many other countries over the world who have studied under Lillian A. Hudson, Associate Professor of Nursing Education, Teachers' College, Columbia University, New York, will be interested to know that she sailed from New York, January 10, on the R. M. S. Franconia to spend a sabbatical leave taking a world cruise. She touches Gibraltar, Monaco, Naples, Cairo, Bombay, Colombo, Madras, Penang, Singapore, Batavia, Bangkok, Saigon, Zamboanga—arriving in Manila March 26 where she will stay until April visiting friends and observing the public health nursing work. She then goes to Hongkong, Shanghai and Tientsin, and on to Peking, where she will be the guest of Anna McCabe and also visit Gertrude Hodgman at the Union Medical College. In July she goes to Japan where she will be the guest of Christine Nuno at St. Lukes Hospital, Tokyo. She will return in time for the opening of Teachers' College in September.—*Abstr. from a letter from M. S.*

* Please send printed matter or other material relating to public health nursing to Eva F. McDougall, 6 State House Annex, Indianapolis, Ind.

Whither Hourly Nursing?—Most people understand pretty well now that visiting nurses give skilled nursing care to the sick in their homes on a visit basis under the direction of the family physician, and that they expect those who can to pay the fee which ranges from \$.75 to \$1.15, depending upon what the actual cost per visit is; if the patient or his family cannot pay the full cost of the visit, they pay what they can, or nothing at all, in some cases.

Now hourly nursing is spreading and people do not understand it as well as the visiting nursing. Hourly nursing is designed primarily for persons requiring skilled nursing care but who do not need the full time of a private nurse. It is administered on the appointment system and charged for by the hour. Fees range from \$1.00 to \$3.00 for the first hour and from \$.50 to \$1.00 for each additional hour—usually the limit of time is 3 hours. This charge pays the cost per visit and there is no charity consideration attached to it.

Dr. C.-E. A. Winslow of Yale said back in 1927, "I hope to see nursing service in the homes of rich and poor—whether on a visitor, on an hourly, or on a daily basis—developed into one co-ordinated scheme of effective community service."

With 3 years of development since Dr. Winslow expressed himself thus, Beatrice Short in *American Journal of Nursing* says, "Just at present hourly nursing is in a stage of rapid development. Until recently, we might say

hourly nursing had been an extension of visiting nursing made available at a definite time at a higher charge per visit. Now, however, all kinds of experiments are under way.

Hourly service is being offered in different places by several methods: by individual nurses; by registries giving calls in turn to nurses devoting their time exclusively to this type of work, or to nurses on call for private duty; by public health nursing associations; or it may be offered under hospital administration; or under a joint committee representing the registry or nurses association, the medical profession, and a public health nursing agency. All plans are meeting with success.

The *Journal of the American Medical Association* says that the nurses' registry of the Chicago Medical Society has established an hourly nursing service.

In this country there is really a serious lack of skilled nursing care for the sick in their homes, while at the same time there is a serious unemployment problem among nurses. Many nursing leaders feel that hourly nursing offers a way of solution, but as Miss Short says:

Fluctuation in the demand for hourly service, difficulties encountered in serving a widely scattered territory, in taking care of sickness and vacation relief, in evolving policies acceptable alike to medical and hourly professions, as well as the communities, must be taken care of. Only a stable organization, with high ideals of service and professional leadership to put these ideals into practice can meet the demand of hourly nursing.

EDUCATION AND PUBLICITY

EVART G. ROUTZAHN*

The Spinach-Eating Motive—We must not merely arouse interest and spread information. *We must get action* or our efforts are useless. In *Hygeia* (Jan., 1931), J. Mace Andress, in "Appealing to the Right Motives," says:

The great problem of health education as well as any kind of education is to find the springs of behavior. . . .

The efficient teacher today realizes that you can get children to do almost anything—eat spinach, drink milk, take exercise, bathe frequently and think straight—if they can be made conscious of certain needs and ways in which these needs may be satisfied. This is another way of saying that the well trained teacher knows how to appeal to children through the right kind of motives. These motives vary with different ages and with different persons. In the lower grades a child may come to school with clean hands because he wants to get a star in the morning inspection.

When pupils reach high school such motives lose their power and others must be chosen that will be more effective. For example, some teachers in commercial departments have been able to get results in cleanliness by telling students that business men are less likely to hire anybody who is not clean and neat in his personal appearance, and that they hesitate to recommend pupils who are careless in personal hygiene. Cleanliness thereby becomes desirable when it is realized that it is a stepping stone to a position. It is not always easy to find a motive that will work, but the teacher is surprised at the lazy pupil who sometimes is inspired to put forth great energy when there is something presented that seems of value to him.

The search for motives and their effective injection into our health education for all ages is the prime challenge to public health workers.

"The Inquiring Reporter"—*Social Hygiene News* recently discovered the following in "The Inquiring Photographer" column of the *New York Daily News*:

. . . replies secured from casual passersby at a busy street corner to the question "Do you endorse the single standard of morals, as advocated by the New York Federation of Women's Clubs?" *The answers from 6 persons*—3 business men, 1 beauty culturist and 2 housewives, were unanimously "Yes, but the standard should be high."

Please send in any personal health questions you have proposed for use by the local "Inquiring Reporter."

Has anyone tried out an arrangement with a local newspaper for a weekly "Inquiring Health Reporter"? And did you submit the same questions and the answers already secured to a physician who could comment crisply and constructively?

A Dozen Marked Copies—Each new publication which you issue is likely to be of interest to certain editors and others who are not on your regular mailing lists. Why not make it an office rule that a specified number of copies, 10 to 15, come to your desk as a routine matter. These copies are for you to send personally to a picked list of those who might be especially interested in that particular publication and those who might be inclined to mention it or base an editorial on it.

If you can write an accompanying letter or memorandum or make it a "marked copy," so much the better.

Be sure to have the copies delivered to your desk where they will be in the way until they are disposed of.

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

Motion Pictures in Germany—As reported in "Methods and Aims of Popular Health Education in Germany," by Professor Adam, secretary-general, Reich Committee on Popular Health Education (*World's Health*, Oct.-Dec., 1930):

The Committee has only a small number of films answering to the special requirements of cinema theatres. The only ones that have proved successful are, perhaps, the films on venereal disease: "False Shame" and "Accursed Heredity." All the other films of this class have failed, and after a short time have been withdrawn from circulation. Very few of the subsidiary films have met with success: the best were those prepared by the Committee itself under the title: "Health without Tears." The witty feature of this film consists of trick drawings, a tiny figure imparting the advice. The contrast between the dimensions of the drawing and the magnitude of the lesson it conveys is in itself amusing. These films were to some extent shown as the final item in the weekly programme; in this way it was possible to give advice on health problems to a public numbering several millions.

Pass It On—*Brookline Health Bulletin* and *Fall River Monthly Bulletin* are among those which "pass on" some of the good things already published in other house organs.

Why not do more of this? There is no particular merit in never repeating the effective messages written by others. All other divisions or bureaus find merit in using the procedures, the forms, the ideas used in common by hundreds of departments.

Talking It Over—Those of the mental hygiene society secretaries who can do so are meeting monthly to talk over their educational methods and materials. The annual sessions of the Public Education Section have a special use and value, but they do not take the place of more frequent and smaller gatherings. School health workers have done more of this than those engaged in popular health education.

Social work publicity councils are to be found in a number of cities. The first issue of *The Councillor* suggests what to do when you get together. *A copy free upon request to the editor of this department.*

"Prepare for Measles Outbreak Now"—What health departments can do about measles was discussed at a general conference attended by 150 people at Albany, N. Y. Among the suggested special services, as reported in *Health News*, New York State Department of Health (Feb. 2, 1931) is the following:

Provide for public instructions through newspaper items, addresses to civic organizations, and, as far as possible, through personal interviews by members of the medical and nursing force with families having young children.

The alert health worker will have a folder of material ready when the department or association program calls for measles publicity, and will have plans for a wider program than the above quotation calls for.

The Education of Givers—The need is illustrated in a readable article, "The Art of Giving," by S. A. Koenig, secretary of Henry Street Settlement. *Saturday Evening Post*. Jan. 31, 1931.

What to tell the giver and the potential giver, and how to tell it is a challenge to our skill and ingenuity.

REPORTING

The Nurse's Bag of the Visiting Nurse Assn., Colorado Springs, Colo., is the most condensed annual report we remember having seen. Half of the inside of the folder is given to a novel array of "bottles" labelled: "Health Supervision—2,854 Visits," "Prenatal Visits—320," and so on. 4 cents.

"It is *not* Far Fetched," says the title of the annual report of the Middletown, N. Y., Health Officer. The report proves that it is possible to produce with

the mimeograph a publication that is dignified, readable looking and amusingly illustrated. It tells what most citizens should know and what many are willing to learn—if properly presented. Dr. Shelley has an enthusiastic, skillful worker with the mimeograph.

Racine Board of Health likewise illustrates mimeograph possibilities. The report is bigger, more expensive, more impressive, and not so popular in style or contents. With a printed cover on attractive cover stock, printed diagrams, and *both contents and index* it is effective beyond many of the printed reports we see.

Texas State Department of Health again uses the mimeograph to produce a special publication. Now it is A Malaria Survey of 20,000 Rural School Children and What It Revealed in Texas. Eight readable pages with illustrations in color. We have asked for a description of the color method.

It looks interesting!—the 60th annual report of the Manhattan Eye, Ear and Throat Hospital, 210 East 64th St., New York, N. Y. The cover is a photograph in strong black and white contrast, with white block in which to print the most inviting contents. Inside photographs which “bleed,” run over the edge of the pages, paragraph captions at the bottom. Case stories, boxed, in small type. Text with headlines: “The Sick Poor: An Increasing Trust—So if we are to continue saying to all ‘Come on in!’—We Shall Need Increasing Gifts.” *Not until page 23* do we find the usual formal annual report title page, which precedes officers, staff, contributors, and so on.

“The High Spots of a 24 Year Program,” was the presidential address before the New Jersey Tuberculosis League, 21 Walnut St., Newark, N. J.

By word and picture the work of the West Virginia Department of Health is explained in its *Quarterly Bulletin*.

Jan., 1931. It is *not* an annual report. The type is a bit too small for the length of line.

The usual impressive report on May Day—National Child Health Day has been issued by American Child Health Assn., for 1930. The state by state reports are worth studying for the bewildering range of activities and ideas accepted in different sections as appropriate to the “Day,” as well as the evidence of widespread coöperation.

What noise does to city dwellers and what we could do about it is reported in *City Noise*, issued by Noise Abatement Commission, Department of Health, New York, N. Y. Much of the material could be used in other cities as is, or could be adapted to other localities. An aerial view of the city for both cover pages, and the chart of noise sources used as end papers, are effective. *Free*.

“A Second Look at First Principles,” by J. B. Pinney. *Journal of Social Hygiene*. Jan., 1931. These “comments on progress in social hygiene, with a record of work for the year 1930,” are supplemented by the Dec. 31, 1930, issue of *Social Hygiene News*. The map showing how different states have been served by the American Social Hygiene Assn., could be adapted to other state or county activities. The figures under “If You Like Statistics” relate largely to educational work.

HOLIDAY GREETINGS

We don't receive nearly all of the published bulletins or house organs, but a goodly share of those seen by the editor carried holiday messages, in addition to much Christmas Seal material.

Ask for copies now and file for inspiration's sake next winter.

The three first are the prize winners.

A cover design featuring “Christmas Health Club Now Forming,” with 3 pages of effective copy in large type—

the whole in red, green and black—on rough finish paper—in non-health-looking envelope—*Health*, Dept. of Health, New Haven, Conn.

"The Gifts of the Wise Men," a full page cover design; inside 3 pages given to three "gifts" of the Wise Men of science—toxin-antitoxin, vaccination and regular examinations—*Bulletin*, Milwaukee Health Dept.

A Christmas Greeting cover and 3 pages of health interpretation of Christmas—all in green and red—*Chicago's Health*, Chicago Health Dept.

A Happy New Year from the Commissioner of Health, and 3 pages on "The Challenge of 1931" in child welfare—*Chicago's Health*, Chicago Health Dept.

"Bonne Annee!" and "A Happy New Year!" messages in parallel columns—*Bulletin Sanitaire*, Provincial Bureau of Health, Montreal, Can.

A page on "Christmas Giving," quoted from Mary E. Richmond in *The Long View*—and a dignified Merry Christmas on the red cover—*Public Health News*, Oakland, Calif.

"Christmas Gifts for Betty," by Sudie E. Pyatt. A shoe-for-the-foot and diamond ring story—*Health Bulletin*, North Carolina Board of Health.

A modernistic Santa Claus surprised in the act and "Healthful New Year" on the cover—and two Christmas stories for the elementary schools—*School Health*, Tuberculosis and Health Society, 51 Warren Ave., West, Detroit, Mich.

"A surgical Santa Claus at the Crippled Children's Hospital"—a "Live to Live" editorial—"Is Santa Claus Dead?" (S. C. in the form of science)—*Pennsylvania's Health*, State Dept. of Health.

Green and red on the cover, official holiday greetings and Christmas in municipal hospitals—*Pittsburgh's Health*, Dept. of Public Health.

A safety message from Santa Claus

and other seasonal copy for publication—*Editor's Clip Sheet*, National Safety Council, 20 North Wacker Drive, Chicago, Ill.

"A New Year's Greeting," with a page of review of health progress and problems—*Health News*, New York State Dept. of Health.

On the cover an appreciation of co-operation, a pledge of service in 1931, and holiday greetings—*Illinois Arrow*, Ill. Tuberculosis Assn., Security Bldg., Springfield, Ill.

The mimeographed bulletin editors did nobly.

"Wishing Ye All A Grade 'A' Xmas"—a tree decorated with "A" bottles—an "old cowhand Santa Claus"—*Echoes from the Cowpen*, the milk standard bulletin, Texas Dept. of Health.

"Connecticut State Department of Health Sends Yuletide Greetings to all those who have Carried the Light of Health and Understanding and thereby Lessened Human Suffering in their Communities"—a sheet in old English accompanying the weekly bulletin.

"Every Connecticut Citizen—His Health Resolution for 1931"—9 resolves—*Weekly Health Bulletin*, Conn. Dept. of Health.

Christmas sketches—paragraphs on candy and toy dangers—a tree on the envelope—*Board of Health Bulletin*, Middletown, N. Y. "Mimeographed by Mildred Dillistin."

"A Merry and—Safe Christmas"—with sketches and advice—*Weekly Health Message*, Iowa Dept. of Health.

Christmas sketches and holiday messages with health morals—*News Letter*, West Virginia Dept. of Health.

NEW

Understanding the Child, Massachusetts Society for Mental Hygiene, 5 Joy St., Boston, Mass. Free to Massachusetts public school teachers. \$1.00 for 4 issues.

An *Industrial Nurse's Bulletin* is announced by New York Tuberculosis and Health Assn., 244 Madison Ave., New York, N. Y.

Illinois Tuberculosis Assn., Springfield, Mass., announces a mimeographed *School Health Bulletin* for teachers. 7 times in the year. From one to 9 copies to one address for 15 cents. Ten or more, 5 cents each.

A mimeographed, blue paper, *Legislative Bulletin*, being issued by Ohio Public Health Assn., Columbus, O., reports on all health proposals in the state legislature.

UNEMPLOYMENT AND PUBLIC HEALTH

A warning against the curtailment of public health programs, issued by Health Commissioner Parran, New York State, suggests that similar action may be desirable elsewhere. *Copy free.*

An experiment in feeding 4 healthy adults on a \$10.42 weekly grocer order is reported in *The Family*, 130 East 22d St., New York, N. Y. Reprints *free*. The suggested menus have been run in some daily papers.

Where health workers are participating in local unemployment activities they may wish to make sure that the leaders or executives have access to *Community Planning in Unemployment Emergencies* published by the Russell Sage Foundation and already distributed to local committees, chambers of commerce and community chests. Where

copies have not been received please write to editor of this department.

Food Thrift—Stretching the Food Dollar, by Jessie G. Cole. State Department of Health, Albany, N. Y. Title of a radio talk and of a pamphlet.

"Two Birds With One Stone." *Health Briefs*, State Department of Health, Nashville, Tenn. Emphasizes giving jobs to the unemployed because

It would hardly be exaggeration to state that there is not a single home in Tennessee that does not harbor some potential menace to the health or safety of that family. Most of these potential health menaces could be eliminated by the members of the family in a few spare hours and others may require the time of a carpenter, pipe fitter, plumber or some other tradesman who is anxious for employment.

DATES AHEAD

April 5-12—National Negro Health Week. Address: National Negro Health Week Committee, Howard University, Washington, D. C. Handbook and Poster. 5 cents each; 100 for \$12.50.

April 27-May 2—National Baby Week. Planned for department stores. Address Editor *Infants' and Children's Department*, Earnshaw Sales Co., 1 East 35th St., New York, N. Y., if interested in coöperating with local stores.

May 12—National Hospital Day. Address: American Hospital Assn., 18 East Division St., Chicago, Ill.

May 21—50th Birthday of American National Red Cross. Meetings or dinners by local chapters.

BOOKS AND REPORTS

Industrial Microbiology—By *Henry Field Smyth and Walter Lord Obold*. Baltimore: *Williams & Wilkins*, 1930. 313 pp., 2 pl. Price, \$6.00.

The function of this volume will probably be to call more widespread attention to the present and the growing importance of microbiological processes in industry. The book should have a distinct place if for no other reason than that it is the first attempt to bring together "what information is available in various scattered sources" since there is "no publication devoted primarily to this phase of mycology." The knowledge in this field is for the most part in a chaotic state. Information is often meager and incomplete. Certain processes have been of importance for centuries while others are almost of the present decade.

In meeting this condition the authors have maintained a completely non-critical style. Most of the book reads like a running abstract and summary of the literature covered. Though no claim is made to exhaustiveness so far as presentation is concerned, the bibliographies furnished seem fairly comprehensive.

The book as a whole covers the field well. The first few sections include discussions of the production of acids, alcohols and ketones. Later the production of certain food preparations and of enzyme preparations is taken up. Very important sections are given over to pointing out deleterious microbic effects as well as beneficial ones, and the modifying activities of organisms in processes which are not purely biological are discussed.

In the present state of our knowledge

a book of this kind must of necessity be more stimulating than informative, and most readers will probably find this true of the present volume. Enough information is available to give an indication as to the possibilities in the field of industrial microbiology, but in very few cases is there enough information to satisfy one's curiosity.

The book is by no means free from typographical errors, but few of them, if any, will cause serious misinterpretations. It gives evidence of a great amount of research, and is to be commended as a pioneer as well as a useful effort in a new direction. Each chapter ends with a good list of references.

ALLEN E. STEARN

Tuberculosis in Man and Lower Animals—By *H. H. Scott*. London: *His Majesty's Stationery Office*, 1930. Price, 4 s. net.

Among the many excellent reports issued by the Medical Research Council of England, this stands preëminent. The author draws on a wide experience with certain classes of human beings and many types of wild animals and birds in captivity. He reasserts the point held by a number of observers, but first, we believe, proved by Schlossmann and Engel, and later by the reviewer with Reichel, that tubercle bacilli may traverse the mucous membrane of the intestine without causing a local lesion, and pass through the lymphatic glands of the mesentery in the same manner. It may be remembered that in the controversy over intestinal tuberculosis, Koch held that before claiming such infection, a lesion should be found in the digestive tract.

Many other interesting features are recounted, and a table is given showing the main findings in 300 cases of human tuberculosis. A curious feature is the rarity of meningeal tuberculosis in animals, even monkeys, as compared with human beings.

Part 2, written in collaboration with John Beattie, gives a description of the lymphatic glands and vessels, too little known and too little taken into consideration by the average student of tuberculosis.

The one point on which we feel inclined to take issue with the author is the determination of the oldest lesion by the comparative amount of caseation and calcification in the neighboring glands.

There are some interesting comparisons between the disease as seen in human beings and in other primates. A study of this report can be recommended unreservedly to all students of tuberculosis.

M. P. RAVENEL

Principles of Women's Athletics—

By Florence A. Somers. New York: Barnes, 1930. 151 pp. Price, \$1.60.

An excellent discussion of the principles involved in women's athletics and of the need and procedures to safeguard adolescent girls and young women in their athletic activities.

The statement of objectives in athletics for women may be summarized as:

1. Provision for the opportunity for every girl to obtain the development inherent in athletic activities
2. The continuation of the play activities of childhood in the more suitable advanced games and sports of the adolescent girl and mature woman
3. The acquiring by the individual of a love for activity and a desire for outdoor recreation which will continue throughout life
4. The opportunity for the adequate social development of the individual through group relationships.

The fundamental factors bearing on the problem are:

A. Biological—does a girlhood of play and activity in sports build strength and endurance for the function of the woman?

B. Physiological—the major function of women being childbearing, the rate of growth in the female differing from that of the male, and the physical stature of the mature woman being different from that of the mature man, what should be our policy?

C. Sociological—the effect of education and custom on the mind of woman in its relation to the qualities sought for or derived from the participation of the modern girl in athletic activities as well as the inherent differences between woman and man.

D. Psychological—sex differences, if any, in mental traits.

Certain trends in athletic competition for girls and women seem dangerous physically, mentally, and socially. The increased popularity of sports has opened the door to unfortunate influences. The tendency toward public competition in athletic sports, which is unfortunately increased by placing women's competition in the Olympic games; the growth of school and town rivalry in which competition for girls is exploited; the type of publicity given girls' and women's sports on our sport pages; the attitude of a mentally abnormal group that women not only can but should do everything that men do; and the commercial phase where athletic clubs use the skill and athletic power of adolescent girls and women as a means of advertising and boosting their club, have made it extremely important that some guidance and control should be given to safeguard our girls and young women.

Attitudes should be developed in girls that shall lead to wholesome ideals and habits of sports. Sports should be chosen that can be used in after life. The selection of these activities should be determined by: sex, age tendencies and interests, needs and capacities, past experience, present facilities, time, and probable future opportunities. Those activities which are outstanding as being most used during leisure time are hiking,

swimming, tennis, dancing, camping, handball, and golf.

The book is concluded by a 10-page bibliography on athletics and other phases of physical education and hygiene. This supplies a much needed, concise, and well compiled statement of conditions and needs that should be in the hands of parents, school and university officials, physicians, and others interested in the welfare of girls and young women. CHARLES H. KEENE

Personal and Community Health—

By Claire Ellsmere Turner (3d ed.). St. Louis: Mosby, 1930. 443 pp. Price, \$2.75.

This convenient little volume is intended for the student at the university, college, normal or professional school. It is comprehensive—possibly unnecessarily so in some directions—covering Personal Health and Community Health with appendices on The Control of Communicable Disease and on Disinfection and Disinfectants. It has a good brief bibliography and a fairly complete index.

One can hardly review a book of this sort without first coming to some conclusion regarding the kind of thing which should be included in texts for the school and college student. Are such books intended to give the student demonstrated facts only or should they include various theories as well? Should the objective be to make him think for himself, especially regarding problems of community health? If so, the pros and cons should be given in detail.

The book under review inclines somewhat toward the magistral method: this being the case, much could be omitted to advantage. Some rather technical things have been emphasized (side chain theory; bacteriophage); unnecessary administrative detail also has been included (as in the section on school hy-

giene and that on the hygiene of reproduction). On the other hand, subjects in the field of preventive medicine, of interest to the layman, are more or less inadequately treated (diphtheria toxin-antitoxin; immunization against scarlet fever). Nutrition, too, hardly gets the balanced treatment which its interest and importance call for. Certain incursions into the medical field are somewhat misleading (as for example reference to incision of the ear drum).

It is easy, however, to find imbalance in most textbooks, especially those of the briefer kind; and criticism too readily becomes captious. On the whole, this book on personal and community health will, as in previous editions, be found most useful, especially in the hands of experienced teachers.

MERRILL E. CHAMPION

Clinical Allergy. Particularly Asthma and Hay Fever. Mechanism and Treatment—*By Francis M. Rackemann, M.D. New York: Macmillan, 1931. 617 pp. Price, \$10.50.*

Few subjects have proved to be of more interest to the physician, physiological chemist, and bacteriologist, and at the same time more puzzling, than allergy. In spite of the great amount of investigation which has been done, the phenomenon still holds many secrets, though much has been learned practically which is constantly being put to use in the treatment of the various manifestations of hypersensitiveness, its cure, and to a certain extent its prevention.

The volume before us is written particularly for the clinician and, as far as this aspect is concerned, it need not be reviewed in our columns. The history, chemistry, immunology, nature and origin of the reaction will be found of interest to those who are concerned in prevention. A truly staggering num-

ment adopted a babies' bib which carried upon it an inscription, "I don't want to be sick, please do not kiss me." This bib was sent to every baby born in Newark during the year. "Parents from all over the country and indeed all over the world wrote in for these bibs and commended the lesson it carried." One young mother wrote, "I have a beautiful baby that everyone wants to kiss, and I did not know how to stop them."

Reference is made to a decrease in puerperal deaths. Besides an increasing number of births in hospitals, it is noted that the Essex County Maternal Welfare Commission has done much in standardizing obstetrical methods and in following up by a questionnaire to the physicians in all cases where death has been reported as due to an accident of childbirth. Here, as elsewhere, it is observed that figures for puerperal deaths would be even more promising if the deaths due to abortion were not included in the total.

As a result of the immunization campaign, children in the kindergarten and first grades of parochial schools were 99 per cent immunized, and the total of all grades was about 70 per cent protected. For the whole city, about 55 per cent of the school children and 10 to 15 per cent of the preschool children have been immunized. No deaths from diphtheria of immunized children occurred.

Greenville, S. C.—In the 1930 annual report, it is noted that 114 cases of communicable diseases were reported during the year, as compared with 244 in 1929. There were no epidemics, no deaths from typhoid or scarlet fever, with 2 deaths (17 cases) from diphtheria. The tuberculosis death rate reported was 18 as compared with 40 in 1929.

A prenatal clinic is held weekly at the city hospital. Patients are care-

fully observed during confinement, and may be admitted free, if worthy, on the Duke Endowment Fund. Baby clinics are conducted twice a week at two hospitals. Indigent children are admitted from these clinics to the wards of the city hospital for the removal, without charge, of diseased adenoids and tonsils.

The chlorination of all dishes, cups, tableware and drinking glasses in places where food and drink are offered for sale to the public, is required by law. The new water supply, provided at Table Rock at a cost of 2 million dollars, is chlorinated. Health education and publicity work is carried on by the health department.

British Columbia—The 1930 report of the Provincial Board of Health indicates that much educational work has been carried on, including the distribution of 240,000 health pamphlets. The 138 Women's Institutes have made public health work the most important branch of their program and have been especially active in the schools.

Excellent photographs add interest to the report. The cultivation of oysters at several points on the coast line has been established on a profitable basis. Logging camps are periodically visited by sanitary officers. Fruit and vegetable canning establishments operate under health department regulations.

The travelling medical health officer reports 1,779 X-ray examinations, an activity made possible by the Christmas Seal sale. One hundred and eighty-six new cases of tuberculosis were thus discovered, besides 137 suspects.

On account of a scarlet fever epidemic in rural schools, a scarlet fever immunization campaign was instituted; 562 children were Dick tested; and 1,957 inoculations were given. In one city also, 688 children were tested and 1,931 inoculations were given, 597 children completing 5 inoculations. An attend-

ance of 3,241 at 108 child welfare clinics in the rural districts is reported. A comprehensive report is made of the work of the Saanich full-time health unit which serves a rural and suburban district about 55 square miles in area, with 14,000 inhabitants. The percentage of attendance in schools has increased from 82.9 before the unit was organized, to 92.4 for the past 2 years. The costs of isolation in the hospital meanwhile decreased from \$1,200 to \$5,500 a year before the unit was organized, to \$350 in 1930. During the past 2 years, 600 children were immunized against diphtheria.

San Diego, Calif.—During 1929, 484 dairy herds comprising 11,145 dairy animals were tuberculin tested and 193, or 1.7 per cent, were found to be reactors and were slaughtered. Two surprise milk contests conducted by the State Bureau of Dairy Control gave an average of over 95 per cent. The purpose of the contests is to check results and methods of the local health department. All laboratory tests obtained by the department between contests, as well as samples taken on the day of the contest, are scored.

A birth rate of 20.1 and a resident death rate of 14 are recorded on the basis of an estimated population of 119,700. An infant mortality rate of 48.7 is noted. Personal injuries and fatalities due to automobile accidents are analyzed. Of 1,042 persons injured, 195 were pedestrians. There were 63 deaths from this cause, 12 of which were of children under 15 years of age. Thirty decedents were occupants of automobiles when the accident occurred, 3 were on motorcycles, 2 on bicycles, 1 on a scooter and the remainder were pedestrians. On the basis of a 1930 population of 147,897, the death rate from accidents that occurred in the city was 35.8. The San Diego Public Safety

Committee, sponsored by the Automobile Club, was organized in 1923 and meets weekly. The Board of Health in 1929 went on record as deploring the loss of life and property damage, due to confusion in laws and lack of proper enforcement, and favored a modern, well equipped traffic bureau. The Police Department traffic division has paid special attention to safeguarding school children.

Providence, R. I.—Reports of the Superintendent of Health, the city registrar, and the inspector of milk of Providence are read with more than usual interest because of their comprehensive nature. The 1929 reports are interesting, enlightening and well printed. The 1930 census recorded a population of 252,981. On the basis of an estimated population of 276,400 in 1929, a birth rate of 20.36, a death rate of 13.12, and a marriage rate of 15.6 were calculated. Total expenditures of the health department in 1929 amounted to \$93,719 as compared with \$88,818 in 1928. A classified financial table shows the details.

The superintendent's report opens with a review of the public health survey conducted in 1929 under the auspices of the Community Fund and a local advisory group by the Committee on Administrative Practice of the American Public Health Association. Several of the recommendations of the survey have already been carried out and others are in progress. On the basis of the *Appraisal Form for Cities*, Providence received a rating for the year 1928 of 817.2 points. The highest ratings were for vital statistics, infant hygiene, and laboratory services.

Six nurses of the health department supervise children delivered by midwives until they are 4 years old, making 14 calls on each well baby before it is one year of age, 4 calls during the 2d

year, and 2 calls a year thereafter. If a baby becomes sick, additional visits are made as indicated. One nurse supervises the infants and young children in licensed boarding homes, and the infants of such unmarried mothers as are not under the nursing service of private agencies. One nurse makes a visit to each infant delivered by a physician provided the mother is not on the maternity service of the District Nursing Association, or is a ward patient at the Lying-in Hospital. Coöperating with the State Children's Bureau, this nurse also visits periodically the licensed maternity homes and some of the day nurseries. The Providence District Nursing Association employs on its children's service 19 staff nurses and 2 pupil nurses, with 2 supervisors. Fifteen child welfare stations were carried on by the Child Welfare Committee, the examining physicians being engaged and paid by the health department. An in-

fant mortality rate of 66 is recorded for 1929, the average for the past 10 years being 74. An excellent statistical table is presented showing deaths of infants by years according to nativity.

During 1929, the city ordinance governing food handlers was amended to allow those willing and able to pay their own physicians for an examination to do so, provided the physician would follow the examination form prescribed by the department. During 1929, 317 persons took advantage of this amendment. In 1929, 5,617 examinations were made at the City Hospital.

One of the several interesting statistical tables gives the unreported cases of communicable diseases discovered by the department and the number without a physician for the past 11 years, with reference to a previous table going back to 1891. This series of reports will be studied with profit by health administrators.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON. PH. D.

Percutaneous Diphtheria Immunization—Administration of diphtheria anatoxin in an oily base (Lowenstein) by rubbing into the skin has advantages which make it the method to be preferred, assert these authors.

ABT, A. F., and FEINGOLD, B. F. Diphtheria Immunization. *Am. J. Dis. Child.*, 41, 1: 8 (Jan.), 1931.

Which Birth Rates Fall?—Those who view with alarm the falling birth rate would do well to pause before this Massachusetts statistical study which finds a slight, but definite, increase in birth rates among native born parents. The much discussed general decline is due to the decrease in the rate among foreign born parents who are growing older, quite obviously.

BIGELOW, G. H., and HAMBLEY, A. D. Our Falling Birth Rate. *New Eng. J. Med.*, 204, 5: 209 (Jan. 29), 1931.

Etiology of Encephalitis—Although we have been spared encephalitis following vaccination, as sanitarians we ought to know the opinions and findings of Europe regarding the phenomenon. This paper seems to be an able dissertation on that and related subjects.

BRAIN, W. R. Zoster, Varicella and Encephalitis. *Brit. M. J.*, 3654: 81 (Jan. 17), 1931.

Value of Health Examinations—For the "hardboiled" critics who are wont to question the true worth of health examinations, there is an answer in this study of the effect of medical examinations on life insurance mortality.

BRITTON, R. O. Effect on Life Insurance Mortality Rates of Rejection of Applicants on the Basis of Medical Examination. *Pub. Health Rep.*, 46, 2: 46 (Jan. 9), 1931.

Etiology of Arthritis—Evidence is presented in support of the proposition that rheumatoid arthritis is a streptococcal infection, in which the streptococci are discharged from a primary focus, circulate in the blood stream, and localize in certain joints where they establish a secondary infection.

CROFT, R. L., *et al.* The Etiology of Rheumatoid Arthritis. *Am. J. Med. Sci.*, 131, 1: 12 (Jan.), 1931.

School Ventilation Again—Two findings are recorded: halving the standard rate of air flow had no demonstrable effect upon the pupils' health, and children in window ventilated rooms were just as free from colds as those in rooms mechanically ventilated.

COLE, R., *et al.* A Study of Ventilation and Respiratory Illness in New York Schools; Comparison of Window-Gravity Ventilation and of Unit Fan Ventilation with Varying Air Flow. *Am. J. Hyg.*, 13, 1: 235 (Jan.), 1931.

What is a Stillbirth?—The variety of definitions of what constitutes a stillbirth, and the effect of the various definitions upon infant mortality statistics will astonish those who have supposed a stillbirth to be always a stillbirth.

GAGNON, G. What Is a Stillbirth? *Canada Pub. Health J.*, 22, 1: 16 (Jan.), 1931.

Filtrable Stages of Bacteria—Among many highly significant demonstrations, the authors of this important communication include the following: the possibility of cultivating in pure lines the filtrable, virus-like stage of a Shiga bacillus, which may be caused to revert to the original cell type with all the original characteristics. The most important contribution of the month to public health literature.

HADLEY, P., *et al.* The Filtrable Forms of

Bacteria: I. A Filtrable Stage in the Life History of the Shiga Dysentery Bacillus. J. Infect. Dis., 48, 1: 1 (Jan.), 1931.

Hearts and High School Athletics—Physical education and athletics may injure the heart. How such injury was avoided in the Pittsburgh High Schools is a worth while contribution to public health literature.

KERR, A. M. Safeguarding the Heart in High School. J. Health & Phys. Ed., 2, 1: 16 (Jan.), 1931.

Tuberculosis Prevention—This excellent, easily understandable account of the operation of the Massachusetts State Health Department's "Chadwick Clinics" tells of the coöperation between the official and voluntary agencies in the preventive measures that follow in the wake of the diagnostic clinics. A lesson badly needed in those states where mutual distrust marks the official-unofficial relationship.

KIERNAN, F. The Social Significance of the Ten Year School Clinic Program for Children in Massachusetts. New Eng. J. Med., 204, 3: 116 (Jan 15), 1931.

Convalescent Measles Serum—A British report of the successful use of pooled convalescent measles serum. This record may be of value to American sanitarians doing research in this field of disease prevention.

NABARRO, D. N., and SIGNY, A. G. Convalescent Serum in Prophylaxis of Measles. Brit. Med. J., 3652: 12 (Jan. 3), 1931.

Physical Education and Health—Sanitarians would do well to read this excellent discussion of the health objectives of physical education which aims to achieve its purpose by building capacity for exercise, freeing the body from handicaps and establishing health habits.

NASH, J. B. Administration of Physical Education and Health in the Light of General Education Needs. J. Health & Phys. Ed., 1, 10: 9 (Dec.), 1930.

Arthritis Control Program—An illuminating discussion of the possibility of a program for the prevention and control of arthritis administered along state lines. Though centered in Massachusetts, the application is nation-wide.

OSGOOD, R. B. The Control of Arthritis. New Eng. J. Med., 204, 2: 55 (Jan. 8), 1931.

Persistence of Diphtheria Immunity—That the antitoxin content of the blood serum obtained by the use of anatoxin does not diminish with time, is the finding of these French researchers.

RAMON, G., *et al.* Value and Duration of Immunity Conferred by Antidiphtheria Anatoxin. Am. J. Dis. Child., 41, 1: 1 (Jan.), 1931.

Water Bacteriology—A new system for the bacteriological examination of water is proposed, which differs from the standard methods, among other ways, by the substitution of crystal violet for brilliant green in culture media.

SALLE, A. J. A System for the Bacteriologic Examination of Water. J. Bact., 20, 6: 381 (Dec.), 1930.

Applied Mental Hygiene—The reasons why mental hygiene cannot be formulated into general rules as is done with physical hygiene are so well stated that this paper is worth study from that angle alone, not to mention other virtues in it.

SULLIVAN, E. A. Mental Hygiene as Applied to the College Freshman. New Eng. J. Med., 204, 2: 62 (Jan. 8), 1931.

Influenza and Social Status—The glib statement that influenza is no respecter of persons will not stand statistical scrutiny. This paper reports a definitely greater fatality especially in older persons, in the lower economic classes.

SYDENSTRICKER, E. The Incidence of Influenza Among Persons of Different Economic Status during the Epidemic of 1918. Pub. Health Rep., 46, 4: 154 (Jan. 23), 1931.

NEWS FROM THE FIELD

CALIFORNIA'S NEW STATE HEALTH OFFICER

GILES S. PORTER has been appointed by Governor James Rolph, Jr., as State Health Officer of California, succeeding Dr. Walter M. Dickie. Dr. Porter has been Deputy Health Officer of Los Angeles for many years, serving under the late Dr. Powers, as well as Dr. Parrish. Dr. George C. Sabichi of Bakersfield has been appointed State Epidemiologist by the Governor.

FRENCH NATIONAL COMMITTEE FOR THE PREVENTION OF BLINDNESS

THE French National Committee for the Prevention of Blindness, similar in aims to the American National Society for the Prevention of Blindness, has recently been formed in Paris. Its president, Dr. de Lapersonne, is also president of the International Association for Prevention of Blindness.

ADDITIONAL CASES OF JAMAICA GINGER PARALYSIS

THE U. S. Public Health Service is in receipt of information which indicates that cases of Jamaica ginger paralysis are still occurring in the United States.

Some months ago it was announced by the Public Health Service that the cause of Jamaica ginger paralysis had been determined to be tri-ortho-cresyl phosphate, which evidently had been used as an adulterant in the manufacture of Jamaica ginger extract.

LEAD POISONING FROM TOYS

LEADING pediatricians announce the occurrence of a number of cases of lead poisoning in infants and children,

apparently due to biting lead paint from cribs, toys, etc. The U. S. Public Health Service has previously called attention to this possible source of lead poisoning but it is likely that more cases occur than become known. Though lead paint has wide fields of usefulness, the painting of babies' toys and cribs is not one of them. It is presumed the manufacturers of these articles will see to it that lead paint is not used for this purpose, but warning is necessary that parents, especially in repainting cribs, should use paints which are free from lead.

THIRTEENTH TEXAS WATER WORKS SHORT SCHOOL

THE Thirteenth Texas Water Works Short School assembled in Waco, Tex.—laboratory sessions January 16-20 and general sessions January 20-23, with 210 total registration. Mineral Wells was selected as the next meeting place.

New officers for 1931 are: L. A. Grimes, Abilene, President; J. D. Rogers, Port Arthur, First Vice-President; Clyde C. Hays, Waco, Second Vice-President; Charles M. Crawford, Childress, Third Vice-President; and Dr. E. P. Schoch, Austin, Fourth Vice-President.

INTERNATIONAL CHILD WELFARE

THE Second International Conference of Social Work will be held in Frankfort-on-Main, Germany, in July, 1932. Its general theme will be social work and the family. The conference will be organized by the executive board of the permanent committee appointed by the First International Conference, which was held in Paris in 1928. Dr.

Alice Masarykova of Czechoslovakia is chairman of the board; and Mary Van Kleeck of New York, as one of the vice-presidents, represents the United States. Applications for membership are received at the Secretariat of the conference, Stiftstrasse 30, Frankfurt-on-Main.

PERSONALS

ANNA E. RICHARDSON, nationally known as an educator and home economist, died in Washington, D. C., on February 3, 1931. She had been suffering from heart trouble for some months, but the end came suddenly.

MARY EMMA SMITH, R.N., of Little Rock, Ark., has been appointed Director of Nursing Activities of the National Society for the Prevention of Blindness, to succeed Mrs. John B. Chambers, who resigned. C. Edith Kerby has been appointed Statistician, a newly created position.

DR. RICHARD R. LYTLE, who for 35 years was contagious disease diagnostician for the New York City Board of Health, died on January 31. He was 78 years old and had practised medicine here until his retirement several years ago.

CONFERENCES

Mar. 23-27, College of Physicians, Baltimore, Md.

Flocculation Experiments with Variola and Vaccinia Virus*

LEON C. HAVENS, M. D., AND CATHERINE R. MAYFIELD

Laboratories of Alabama State Board of Health, Montgomery, Ala.

IMMUNOLOGICAL studies of viruses have shown clearly and uniformly that virucidal properties are developed in the serum of animals following an attack of the disease and in some instances following injection of the killed virus. The demonstration of agglutinins, precipitins or complement-fixing antibodies has not been so convincing and, in contrast to bacterial antigens, doubt exists whether the viruses, as a class, are capable of stimulating such antibodies. Fairly clear-cut evidence, both for and against their existence, has been recorded.

Gordon¹ has described specific complement-fixation and flocculation with vaccinia and variola, and Burgess, Craigie and Tulloch² have utilized the flocculation test as a practical diagnostic procedure for the differentiation of smallpox and chicken pox. Takaki and Koref³ used complement-fixation to identify the viruses of herpes, rabies and encephalitis. Ciuca⁴ reports successful complement-fixation experiments with the virus of foot and mouth disease and Bedson and Bland,⁵ in addition to a number of other investigators, have confirmed Gordon's results with vaccinia. Recently, Frobisher⁶ has reported complement-fixation reactions with the virus of yellow fever and the serums of men and monkeys.

In contrast to these findings, indicating that viruses are similar to bacterial antigens in the production of antibodies, Schultz, Bullock and Lawrence,⁷ among others, were unable to demonstrate any other than specific neutralizing antibodies in the serum of rabbits immunized against vaccinia. Ward⁸ reports negative complement-fixation experi-

* Read before the Laboratory Section of the American Public Health Association at the Fifty-ninth Annual Meeting at Fort Worth, Tex., October 29, 1930.

It is our purpose to describe the production of anti-vaccinia flocculating serum in the rabbit and in the human subject, the successful demonstration of specific flocculation of vaccinia virus by its antiserum, as well as observations of the usefulness of the reaction as a practical diagnostic test.

Serums Nos. 1, 2, 3 and 4 were obtained from rabbits vaccinated intradermally with 2d passage rabbit dermal virus. The backs were

denuded of hair from the shoulders to the flanks, the skin scarified and inoculated with vaccinia virus harvested from another rabbit similarly vaccinated. These serums, obtained 12–14 days following inoculation, yielded on the whole as satisfactory titers as those obtained by intravenous and subcutaneous inoculations. Two rabbits, inoculated intraperitoneally, according to the general scheme of the intravenous and subcutaneous injections, failed to yield a flocculating serum. The rabbits were bled from the heart, the serums removed from the clots and stored under aseptic conditions without addition of preservative and without inactivation.

We have not succeeded in obtaining in the rabbit a higher titer than 1:64, either with dermal or brain virus. Efforts to increase the potency of the serum by injecting large amounts of virus failed, particularly in the case of the brain virus, due to the fact that intravenous injections of brain tissue in amounts larger than 0.5 c.c. of a 1:20 suspension usually caused immediately fatal convulsions. Subcutaneous injections of brain virus up to 0.4 gm. failed, in the case of 2 rabbits, to produce a higher titer than 1:32. The titrations of the serums are given in Table II.

 0 = Not tested

Preparation of the Antigens for the Tests—The antigens used in the tests, whether of dermal or brain origin, were first ground in a mortar with the addition of small amounts of 0.85 per cent sodium chloride solution. After thorough grinding and further dilution with

salt solution to make an approximate 1:100 suspension, the material was centrifugated for 2 minutes at 2,000 r.p.m. The supernatant suspension was then diluted until the turbidity was equal to that of BaSO₄ standard No. 1. This was found to be approximately the turbidity of the supernatant of a 1:100 suspension of rabbit brain after centrifugation. Where more dilute antigenic suspensions were used, they were prepared by dilution of the 1:100 suspensions with salt solution. Usually 1:100 suspensions, which, after centrifugation, were only slightly turbid, gave satisfactory results, but in some experiments more dilute antigens, even 1:1,000, flocculated well (see Table IX). As a rule, heavier suspensions, such as 1:20 or 1:50, did not give as heavy a precipitate as did 1:100 or even more dilute. This is illustrated with a brain virus in Table IV.

Titration of Potency of Antigens—The potency of all antigens, both dermal and brain, was determined by intradermal injection into the denuded backs of rabbits of 0.05 c.c. amounts of serial dilutions of the virus. The titer of a given virus was taken as the highest dilution which caused a definite lesion.

Technic of the Tests—Serological tubes (10 x 100 mm.) were used. Serial dilutions of the flocculating serum were placed in the tubes in 0.3 c.c. amounts and to each was added 0.3 c.c. of the antigenic suspension. Controls with salt solution and normal rabbit serum were included for each antigen. The tests were incubated in a water bath at 37° C., readings usually being made at 1, 2, 4, 6 and 18 hours. When the titer of a serum was being determined the 24-hour reading was taken as final.

A few ring tests were also made, both with undiluted serum and serial dilutions of antigen, and *vice versa*. While a definite ring usually formed with appropriate dilutions of antigen or serum, the results, on the whole, were not so clear-cut as with flocculation. Incubation of the tests at 56° C., as recommended by Gordon¹ and Burgess, Craigie and Tulloch,² gave indifferent results. The amount of flocculation was never great and rarely occurred except in low dilutions of serum.

Specificity of the Reaction—The unequivocal and consistent flocculation obtained with brain vaccinia and immune serum prepared by injection of brain virus can hardly be interpreted in any other way than as the result of a specific reaction between vaccinia virus and the immune serum. In view of negative results reported by Schultz and his coworkers³ with brain virus free of bacteria and his contention that the precipitation obtained with dermal virus was due to contaminating bacteria, this point has been investigated and the absorption experiments described by Burgess, Craigie and Tulloch repeated.

Serum (0.3 c.c.) absorbed with 1.2 c.c. of 1-10 suspension of washed and packed bacteria (centrifuged 2,000 r.p.m. for 20 minutes)

Serum (0.5 c.c.) absorbed with 2.0 c.c. of 1:20 suspension dermal virus

Absorption for 1 hour at 37° C.

The serum of every rabbit which we have examined, some 2 dozen in all, contains agglutinins, occasionally in dilutions as high as 1:128, for one or more of 8 or 10 strains of bacteria, mostly staphylococci, isolated from rabbit skin and dermal (rabbit) vaccinia virus. Furthermore, when dermal virus is used for immunization, the titer of the serum for some of these staphylococci is frequently raised, due to their presence in the crusts from which the suspensions for injection are prepared. The rabbits (5 in number) immunized with brain virus, free of ordinary bacteria, have all yielded an unchanged titer for these organisms, following the course of immunization.

The results of absorption tests with 3 different strains of staphylococci (S1, S2, and S3) and 4 anti-vaccinia flocculating serums are given in Table III. The results lead to the conclusion that the flocculation obtained with vaccinia virus, either dermal or brain, is specific. Removal of the antibodies for the staphylococcus strains did not affect the flocculating properties of the serum for the virus. On the other hand, removal of the vaccinia antibodies by absorption with dermal virus left the agglutinins and precipitins for the staphylococci unchanged.

The experiments further show that, as Smith⁹ has observed, viruses behave in the same way as bacteria in respect to the specific absorption of antibodies. There is one difference, however, which may be more apparent than real, although it has been noted by other observers, such as Burgess, Craigie and Tulloch,² and Andrewes,¹⁰ as well as

Smith. This is in the seemingly large amount of vaccinia antigen required for complete removal of the antibodies, even from a serum of comparatively low titer. We have observed that under conditions of our experiments, approximately 0.1 gm. of dried dermal virus (potency 1:8,000) or 2 c.c. of 1:20 centrifuged suspension is required to absorb completely the flocculating antibodies from 0.5 c.c. of serums which have a titer of 1:32–1:64. Compared with the number of bacteria required for complete absorption of specific agglutinins from antibacterial serums many times more active than anti-vaccinia flocculating serum, the amount of virus required for absorption of the latter seems excessively large.

We may assume, however, that in a virus of a potency such that 0.05 c.c. of a 1:8,000 dilution is the smallest amount which will produce a lesion after intradermal injection, the specific antigen present is a very small part of the whole and may be comparable to the amount necessary for absorption in the case of bacterial agglutinins.

Effect of Varying Concentrations of Antigen—That optimum concentrations of antigen for flocculation exist is indicated by the results with a brain virus recorded in Table IV. It is seen that concentrations greater than 1:50 failed to flocculate, whereas the best results were obtained with concentrations around 1:100.

Diagnostic Tests with Scabs from Chicken Pox and Smallpox Patients—In Table V are given the results of flocculation tests with 42 specimens collected from clinical cases of smallpox, vaccinia and chicken pox. Material was obtained from 28 cases of chicken pox, 9 cases of smallpox and 5 human vaccinations. The scabs were prepared for the tests according to the method already described for the

preparation of the antigens. Whenever there was sufficient material it was tested against 3 flocculating serums in addition to normal rabbit serum, but in several instances there was sufficient antigen for tests with only 1 or 2 serums. The tests were incubated at 37° C. and read at intervals, the results recorded in Table V being those obtained at the end of 24 hours.

While the series is small, certain facts are apparent. In the first place, 10, or 35 per cent of the tests with chicken pox material, were positive with one or more of the anti-vaccinia serums. That the flocculation which occurred was nonspecific is indicated by its occurrence also in the tubes containing normal serum.

N 2 = Serum of normal rabbit. For description of other serums see Tables I and II
 Figures refer to highest dilution of serum in which definite clumping occurred

The tests with smallpox and vaccinia scabs were all strongly positive but in 4 instances (17, 34, 37 and 38) flocculation occurred with normal serum to such an extent as to throw doubt on the specificity. The frequency with which flocculation occurred in normal rabbit serum is in striking contrast to the results obtained with rabbit virus and is apparently contrary to the clear-cut results of the series reported by Burgess, Craigie and Tulloch. The reaction, as a diagnostic procedure, with the technic used, becomes valueless, due to the difficulty of interpreting the results.

Effect of Concomitant Bacteria on Specificity of Result—In view of the presence in rabbit serum of agglutinins for certain staphylococci, it was thought that this might be the cause of the nonspecific flocculation so frequently encountered. To test this possibility, cultures were

made from suspensions of several smallpox and chicken pox scabs and representative staphylococci isolated were tested with the rabbit serums which we have used. The results with 2 strains which were most universally agglutinated are given in Table VI. All but one of the serums agglutinated these 2 cultures (24-4 and 32-1), some in comparatively high titer.

Table VII summarizes the results obtained when three anti-vaccinia serums and one normal rabbit serum were absorbed with suspensions of chicken pox scabs and with cultures of staphylococci isolated from them. It is seen that when the serums were so absorbed the titer for the homologous culture and suspension was reduced, while the flocculating properties for a smallpox antigen (17 S) and for vaccinia virus were not affected.

Effect of Incubation Time on Specific Flocculation—The results of the tests presented in Table V are the readings obtained after 24 hours' incubation. It was noted that frequently flocculation had occurred after only 1 or 2 hours in the water bath, particularly in the lower dilutions of serum. In Table VIII are presented the results obtained after different incubation periods with 16 antigens and 3 immune

serums. After incubation for 1 hour, flocculation had occurred in one or more tubes with at least 1 immune serum in the case of 9 vaccinia and smallpox antigens, while no flocculation had appeared with 4 antigens. Only 1 antigen (38S) had flocculated in normal rabbit serum and this was in the first dilution only (1:8). None of the chicken pox antigens flocculated, although they were chosen because of their ability to flocculate well in normal rabbit serum. After 2 hours' incubation all but 2 of the vaccinia and variola antigens had flocculated but 5 had started to flocculate in the normal serum also, and the chicken pox antigens had begun to show precipitation. After 4 hours, the nonspecific flocculation had increased, and after 18 hours only 6 antigens were negative in the normal serum, while the chicken pox suspensions had flocculated in each of the serums tested.

N = Normal rabbit serum

For description of serums 6 and 8 see Tables I and II

Figures refer to highest dilution of serum yielding definite flocculation

Effect of Dilution of Antigen on Specificity—Tests have also been made with increasing dilutions of antigens. Parallel tests with 1:100, 1:200, 1:500 and 1:1,000 dilutions of 15 vaccinia and variola antigens and 6 chicken pox antigens are presented in Table IX. The results are those obtained after 18 hours' incubation at 37° C. It is readily apparent that dilution of the suspensions of chicken pox scabs to 1:1,000 yielded negative results, while the vaccinia and variola antigens still flocculated, most of them as strongly as in lower dilutions. The results with normal rabbit serum were more consistently negative than in the lower dilutions.

Development of Precipitins in Human Serum—Since the vaccinated rabbit responds with the appearance of specific precipitins in its serum, the question arose whether the serum of vaccinated persons also acquired this property. Observations have been made on 4 persons (Table X), never vaccinated before, with the exception of No. 4, who gave a doubtful history of a successful vaccination 20 years ago. In all the vaccination followed a typical course. Specimens of their blood were obtained at the time of vaccination, on the 10th day following, and from 3, on the 17th day. Each serum was set up with a rabbit brain vaccinia suspension (1:200) of which the potency was 1:175,000, and in each instance, also, with a 1:200 suspension of a normal rabbit brain. It is seen that the serum of each individual

showed, following the vaccination, an increasing titer, from 1:8 or less, to a maximum, on the 17th day, of 1:64, and in 1 case 1:128.

In addition to these observations on the appearance of precipitins following vaccination, the serums of 19 immune persons have been tested for the presence of flocculating properties. All were vaccinated at the time the blood was obtained, with the exception of No. 9, who refused, and No. 22 and No. 23, who were convalescent from smallpox. The results are summarized in Table XI. The serums of 5 persons apparently contained precipitins for normal rabbit brain tissue, 1 (No. 19) yielding a precipitate in 1:16 dilution of the serum, the others in 1:8. Only 3 of the immune persons gave entirely negative results, but since the serum of 1 of the non-immunes (No. 1) flocculated the virus in a dilution of 1:8, it is questionable whether results in such low dilutions are significant. On the other hand, the serum of 1 person (No. 12), who was successfully vaccinated 20 years ago, flocculated in a dilution of 1:64, as high a titer as the serums of the smallpox convalescents. It seems obvious, at least, that a negative flocculation test cannot be taken as an indication of lack of immunity.

DISCUSSION

The experimental evidence obtained is in support of previous observations of other workers who have concluded that vaccinia virus behaves like bacterial antigens in the production of antibodies. It is difficult to explain the clear-cut results with uncontaminated brain antigen in any other way. The experiments in which the agglutinins for concomitant bacteria in dermal virus were absorbed from the serum without affecting its flocculating value for vaccinia virus corroborate this view. Furthermore, the experiments of Maitland and Laing,¹¹ who obtained positive complement fixation with pure cultures of vaccinia virus, can hardly be considered otherwise than as an example of specific antigen—antibody union.

An explanation for the negative results which have been reported may be found, in certain instances at least, in differences of technic. Concentrations of antigen greater than a certain optimum dilution may prevent visible flocculation. While we have in the work reported here held to certain definite dilutions of the antigens, the impression has been gained that, in the case of most antigens, dilution to the point of opalescence, rather than a definite turbidity, yields the most satisfactory results. No exact statement can be made, because the original concentration of virus in the material used can be determined only by animal inoculation.

The ring test, in our experience, does not produce such consistent

results, nor in such high dilutions of serum, as does the flocculation technic. This observation might be interpreted as constituting evidence that the reaction is akin to agglutination rather than precipitation; however, a definite statement is impossible and probably unimportant.

When we come to the application of the reaction as a practical test for the differential diagnosis of smallpox and chicken pox, our experience is discouraging. The occurrence of agglutinins in many rabbit serums for strains of staphylococci found in human chicken pox and variolous material confuses the result, in many cases due to agglutination of these organisms in the normal rabbit serum controls. That Burgess, Craigie and Tulloch encountered the same difficulty in their series is indicated by their statement, "We have on four occasions observed a peculiar reaction to occur when crust extracts have been exposed to rabbit serum, both anti-vaccinia and normal." They claim, however, that the nonspecific reaction which they observed was easily differentiated from the specific precipitation by the size and looseness of the clumps. However this may be, the number of such reactions in our series is apparently larger than theirs and the clumps were sufficiently similar, both in size and character, to the specific clumps, as to make differentiation difficult, if not impossible.

The results obtained in the rather small series where the effect of serial dilutions of the antigens was compared are more encouraging. The observations, though limited in number, indicate that in most cases, at least, at a dilution where the concomitant bacteria fail to give a reaction, the virus is still present in sufficient quantity to cause definite flocculation. Further observations are being made to determine this point.

The results obtained when rabbit neuro-vaccine was tested against human immune serum are entirely analogous to those obtained with immune serum prepared in the rabbit. The results in Table XI indicate that the flocculating properties of the serum do not persist so long as the immunity to the disease, and are therefore not indicative of the immunity status. The vaccinated individuals, whose serum reactions are given in Table X, are being followed to determine how long the reaction persists. The fact that these serums flocculated the virus as early as the 10th day after vaccination, i.e., about the 7th day of the disease, raises the possibility that this early appearance of precipitins may be utilized as a diagnostic aid in the human disease.

SUMMARY

Experimental evidence indicates that the intradermal or intra-

venous inoculation of vaccinia virus in rabbits is followed by the appearance of specific flocculating properties in their serum.

Vaccination of the human subject stimulates the production of precipitins against vaccinia virus. The serum of 4 persons acquired this power to flocculate the virus as early as the 10th day following vaccination.

Milk Consumption and the Growth of School Children

UNDER the auspices of the Department of Health for Scotland, 10,000 children in the Lanarkshire schools were given $\frac{3}{4}$ pint of raw or pasteurized milk every day from February to June, 1930, and compared with 10,000 other children not so favored.

The result, as in similar but less extensive tests in previous years, showed a definite increase in the rate of growth of the milk-fed group. This increase was the same for raw and pasteurized milk. There was no obvious difference between boys and girls, and little evidence of definite relation between the age of the children and the amount of improvement.

Once again the unsurpassed value of pure milk as the chief contributor to the healthy growth of school children has been demonstrated. Whatever else may be said about the alleged thrift of the Scotch, they have been generous in the nourishment of these children of school age. Their example is worthy of universal emulation.—Gerald Leighton and Peter L. McKinlay, Edinburgh, H. M. Stationery Office, 1930. Abst. James A. Tobey.

Smoke Eradication to Save the Health Value of Urban Sunshine^{*}

FRED O. TONNEY, M. D., F. A. P. H. A., AND CLARENCE

R. DEYOUNG

Bureau of Laboratories and Research, Department of Health, Chicago, Ill.

THE loss of the shorter ultra-violet rays of sunshine, due to atmospheric pollution, is beginning to be recognized as a health problem of cities.

That the loss is constant and of sufficient proportions to be of health concern is indicated by recent studies in several American cities. In Chicago, both by spectrographic¹ and chemical methods,² a decided loss of short rays and actinic intensity was shown during most of the year and an unusually long period of low ultra-violet light in sunshine (7 months) was demonstrated. More recent studies in Chicago³ have shown that smoke is a very significant factor in the loss of actinic rays, even in summer, the season of minimum combustion of fuel.

In Baltimore, Shrader, Coblentz, *et al.*⁴ reported a loss of about 50 per cent in solar ultra-violet light as determined by actinic methods.

In New York City, Ives,⁵ in a study of sunshine measured by the photoelectric cell, showed a loss of 50 per cent in visible light, without respect to ultra-violet light.

Efforts to abate the smoke of ordinary fuels to a sufficient degree to save the ultra-violet light of sunshine have thus far proved inadequate. The results have been apparent in greater visibility, cleanliness and economy of fuel rather than in material saving of ultra-violet light.

In Pittsburgh,⁶ an intensive 10-year program of smoke abatement by forced draught combustion methods succeeded in reducing the visible smoke due to unburned tarry matter, but increased the total deposit of dust particles in the air about 40 per cent. Although the dust of ash particles, according to recent experiments,⁷ is somewhat less opaque to ultra-violet light than that of soot and tarry matter, it is nevertheless definitely opaque, and the greatly increased amount of

^{*} Read at a Joint Session of the Public Health Engineering and Industrial Hygiene Sections of the American Public Health Association at the Fifty-ninth Annual Meeting at Fort Worth, Tex., October 30, 1930.

FIGURE I—The smoke problem in Chicago

ash dust would seem to offset the advantage of complete combustion by forced draught.

In Chicago one has only to look out over the downtown district from a loop tower or airplane on a bright summer day to realize the practical futility of control methods applied to the present combustion processes, with respect to conservation of ultra-violet light.

As seen from above, even when combustion is at its minimum, a vast cloud hangs almost continually over the city, the massed contributions of thousands of stacks, each contributing a little, but each for the most part innocent of violation of any sane and reasonable anti-smoke regulation.

It appears therefore that there is little hope of restoring the lost sunshine of cities by smoke control methods applied to the usual combustion processes.

A changed point of view is needed—a new objective to direct engineering thought toward a really effective solution of the problem as a whole, with its health aspects, as well as the esthetic and economic.

That objective, we believe, should be “smoke eradication” rather than “smoke control,” and its motivation should place foremost and above all other considerations the needs of the public health. Its slogan should be: “Sunshine of full actinic value, for urban as well as rural populations. (1) To assure normal growth of children; (2) To build sound, straight teeth and strong bones; (3) To eradicate rickets in infants; and (4) To help maintain resistance to those diseases which attack when vitality is low.”

FIGURE II—Two pictures taken at the same time from Foreman Tower: (1) View east toward lake. (2) View west toward Civic Opera Building

Figures III and IV are presented for study and critical analysis, rather than as a basis for any contention or conclusion. They offer data on the relation of (a) total deaths per month, and (b) deaths from acute respiratory disease per month, to (c) the total sunshine hours per month and (d) the erythema hours of sunshine per month, during 1926-1927 in Chicago.

FIGURE III—Relation of total deaths to erythema hours of sunshine per month in Chicago, 1926-1927

FIGURE IV—Relation of deaths from acute respiratory disease to erythema hours of sunshine per month in Chicago, 1926-1927

The striking feature of these charts is a remarkable correlation between respiratory disease deaths and erythema hours per month, which is not so obvious in any of the other relationships.

Low erythema hours are observed to be followed by high respiratory death rates with a "lag" of 1 to 2 months, and conversely the higher erythema hours per month are followed by correspondingly lower respiratory death rates, after a similar "lag."

THE REMEDY

What promise of really effective smoke eradication may we find in the present state of knowledge to save the sunshine of cities? As a basis for constructive thought and discussion of the practical possibilities, we present 3 suggestions to the engineering profession, which, if they are sound, may help to direct the trend of development.

1. Steam heating from a central plant, serving a large district as a public utility
2. Gas heating
3. Electric heating

THE CENTRAL STEAM HEATING PLANT

The central steam heating plant serving groups of buildings through underground connections is familiar to all, but operating as a "public utility" over a radius of several miles, it is a relatively new development. Such plants appear to be well adapted to congested districts and apparently can compete successfully with individual heating plants, through greater economy in operating costs and larger purchasing power. From the standpoint of smoke abatement, a single stack, representing an efficient and well managed plant, is a welcome substitute for thousands of small plants, many of which are poorly equipped and carelessly operated. Even the minimal smoke accumulation of many small plants inevitably produces a smoke pall, while the same fuel, burned in a single well equipped and competently fired installation, should be relatively innocuous.

"Mariemont," a suburb of Cincinnati, O., illustrates this type of development in a newly built, well planned residence district. The central steam heating plant is now operating in several of the larger American cities, including Cleveland, O., Detroit, Mich., Kansas City, Mo., St. Louis, Mo., Pittsburgh, Pa., and New York, N. Y. Progress toward smoke eradication by this method is necessarily slow and also it seems applicable only under special conditions. However, it deserves consideration as a potential method to be used in combination with the other available methods.

GAS HEATING

The use of both artificial and natural gas in heating and industrial processes is now on the threshold of wide development. Pipe lines are being extended from the natural gas fields to the larger cities, including Chicago. Gas heating appliances may be readily fitted into existing boiler equipment and by reason of automatic control and the elimination of handling, hauling, and storage costs, gas is beginning to compete with other fuels.

Gas combustion is practically complete. The products are gaseous in nature and should contain no ash or other solid particles. Theoretically, at least, the burned effluent of gas combustion should not occlude the ultra-violet light of sunshine. Heretofore, however, there have been no data on this point.

To make a practical test of the possible screening effect upon the actinic light rays of atmospheric accumulations from gas combustion on a large scale, experiments were recently conducted by us in Tulsa and Oklahoma City, Okla., and in Fort Worth and Dallas, Tex., which are essentially gas heated cities. The actinic method was used.²

FIGURE V

Figure V shows the average hourly actinic readings between 10 A.M. and 4 P.M. standard time, in the residence and business sections of the 4 cities on clear days, as compared to simultaneous readings in the nearby country, the latter locations being designated as "clear points." The maximum and minimum daily temperatures during the tests ranged from 42–57° F. for Tulsa to 52–76° F. for Dallas.

Figure VI illustrates the hourly differences between the urban and rural readings for a single day in Tulsa, Okla. The noticeable actinic loss between 10 A.M. and 11 A.M. in the residential district was apparently due to coal smoke from locomotives in a railroad yard to the windward. At the next hour the testing station was shifted to the other side of the railroad and thereafter readings closely approximating those of the "clear point" were obtained.

Both charts are to be considered in comparison with Figure VII, representing the similar average findings by months in Chicago, especially from April to August inclusive, the season of minimal combustion for heating purposes.

In the southern cities the proportionate loss of actinic rays of erythema intensity* from the smoke of gas combustion was very

* Actinic intensities of erythema quality are those on or above the line indicating minimal erythema dose.

small compared to the loss in Chicago where coal is the principal fuel.

Of the gas heated cities, Oklahoma City showed the greatest actinic loss with an estimated percentage of about 80 per cent of buildings heated by gas as compared to about 90 per cent for Fort Worth, and 95 per cent for the other 2 cities. The other fuel used is principally oil, but considerable coal is still being burned in Oklahoma City.

In Tulsa an opportunity was presented to test an oil burning district (Figure VI) and here a greater loss of actinic sunshine was demonstrated.

FIGURE VI

From the standpoint of smoke eradication, gas heating appears to offer greater promise of early relief than any of the other methods. It requires no revolutionary changes in building construction or heating equipment. It is equally applicable to old and new heating appliances. It can be placed in small and large plants alike. It may be extended rapidly, and brought to serve large areas within a relatively short time.

Possibly gas heating may not be the ideal ultimate solution of the smoke problem of cities, but it has the advantage of being already at hand. The possibilities of objectionable effects of accumulated gas-

FIGURE VII—Average actinic intensities for four city districts and for clear points. Hourly observations between 11 a.m. and 3 p.m.

ous products of combustion in the atmosphere are yet to be studied, but in any case immediate and decided improvement is certain and a means is available of bridging the gap between the present highly objectionable combustion methods and slowly evolving methods of the future.

A new residential suburb "Sauganash" located in the northwestern section of Chicago is largely a community of gas heated homes. An airplane view of the project is shown in Figure VIII. It will be noted that there is no visible smoke emission from the gas heated homes in the foreground, but many smoke columns are to be seen in the city proper in the background.

ELECTRIC HEATING

Until recently, the prospect of electric heating as the ideal goal of heating methods seemed far remote and to be thought of only for our children's sake. The idea is highly attractive—cleanliness, convenience, complete absence of smoke; fuel burned at a distance from the city and converted into current; hydroelectric power developed to its maximum possibilities. From a health aspect the picture is perfect, and it appeared to be a trend consistent with previous development of electric light and power.

But the cost, we were advised, is prohibitive. The loss of energy in conversion of electric current into heat is greater than in its conversion to light and power. Coal cannot be burned at the mines unless an abundant water supply is at hand. Current cannot be carried more than 300 miles without excessive loss. "There is not enough potential electric energy available to heat the City of Chicago," we were told.

But who knows what compensatory saving there may be in electric heating, once it is established on an extended scale? Charges for fuel transportation by rail, unloading at the yard, reloading, cartage, repeated handling until it reaches thousands of individual plants, janitors shoveling coal and tending furnace, ashes to be hauled, repairs and maintenance, waste of fuel—smoke—all these leaks are costly. Perhaps in electric heating as in gas heating there would be added saving in quick availability—heat at once when and where needed, and saved at once where not needed—no loss in the building up or dying down of fires. Again perhaps there may be material saving in the "inter

Chicago Aerial Survey Co

FIGURE VIII—Sauganash

peak" usage of current supplied through regular channels for ordinary demands. And this brings us to the most recent offering in electric heating, and *again stirs hope!*

Figure IX shows a house heating plan utilizing electric current at "off peak" hours, 11 P.M. to 6 A.M., to heat a well insulated tank of water under pressure to a temperature of 250° F. Thence during the day hot water or hot air heat is delivered by automatic control throughout the house, and at a current cost aggregating but little more than the usual heating costs of a home!

A community of the better type of homes, electrically heated by this method, is now developing in Fort Wayne, Ind., where rate concessions for "off peak" current have been allowed.

In LaGrange, Ill., a suburb of Chicago, a single electrically heated home knocks at our door, awaiting similar rate concessions to make electric heating an actuality in the metropolitan area. A few years ago, it was a dream. Today electric heating is here. The prospective electrification of rail terminals and suburban roads is in line with the trend toward greater peaks and emphasizes the economic desirability of a market for "off peak" current.

FIGURE IX—Plan of an electrically heated home utilizing "off peak" current

THE FUTURE

What a prospect—electric heating, gas heating and the central steam plant developing hand in hand, each seeking its most favorable outlet, according to its special fitness, electric heat to the finest suburban homes, gas heat to the city proper and to the industries, and central steam heating to the more congested districts. Smoke will be of the past, no longer a menace to health, robbing the children of needed sunshine.

Let us look for a moment toward the city of the future—clean with the cleanliness of health, with clean, invigorating air and undiminished sunshine, white buildings that stay white, clean linens, clean faces.

The health benefits of the country brought to the back yards of the most congested districts: Ruddy complexions like those of vacation days showing adequate dosage of ultra-violet light; healthy, normally growing children with even teeth, straight bones, and a high resistance to disease; a vigorous, active population of workers, producing effectively, living, working, enjoying—in an atmosphere of health.

Some day all this will be a reality. The basic knowledge just now coming to light will force the change, and no one can hold back or block its progress. But we, as health advisers, can speed the change and ourselves participate in its benefits. We can point the way. We can enlighten. We can fight for our convictions, to hasten the transition of the dingy, smoky city of today to the clean and healthful city of tomorrow.

What of the next few years? The rate for 1930 is lower than before, but 253 deaths is a terrible sacrifice to make to the little dirty gods of Ignorance and Carelessness.—*Health Bull.*, N. C. State Board of Health, Mar., 1931.

Challenge of Malaria in the South *

JOHN A. FERRELL, M. D., DR. P. H., F. A. P. H. A.

International Health Division, Rockefeller Foundation, New York, N. Y.

ALL studies of the distribution, importance and trends of malaria with which I am familiar have involved consideration of methods for its measurement. No single method of measurement is ideal for use by the ordinary local health organization. Methods which can be employed by the malaria specialist are expensive, and unfortunately there are few real malariologists. As a consequence, accurate and full information is available only for limited areas and for brief periods. Where a systematic collection of all available data has been made, the malaria trends, as based upon personal histories, doctors' records, morbidity records, spleen examinations, blood examinations, and mortality records, are all in general corroborative.

Mortality records of malaria afford the only reasonably complete index available for the entire area of malaria importance. It is known that these records contain inaccuracies and are often misleading. Deaths from malaria contracted elsewhere are recorded in localities in which no transmission of the disease occurs. Again, malaria transmission may be important in a community, impairing the health and working efficiency of the inhabitants without actually causing deaths from the disease. Cities, counties, and other communities, however, which show an appreciable number of deaths of residents from year to year due to malaria can, as a rule, be regarded as having a malaria problem. It should be observed that the total number of deaths occurring in a state where malaria is restricted to a small area may be so few as to suggest that the disease is unimportant, and yet in communities where malaria does occur, it may be the major health problem. Although malaria has rendered many places uninhabitable, it has rarely reached such a degree of severity in this country—certainly this applies to the past decade or two.

In using mortality statistics as a basis for this discussion, it is believed that in spite of the inaccuracies and limitations of the statistics, they do give a true picture of trends over large areas. If a particular city or county were being studied to determine whether malaria consti-

* Read before the Public Health Engineering Section of the American Public Health Association at the Fifty-ninth Annual Meeting at Fort Worth, Tex., October 28, 1930.

tuted a public health problem warranting special administrative procedures against it, and if so, what procedures, the approach would have to be quite different. The focuses of infection and of quadrimaculatus breeding would have to be studied and their relations determined. The type of control measure to be applied in each area would depend on local conditions. In one locality drainage might be practicable, whereas in another screening or other measures would be chosen. Again, a combination of measures would be indicated. Our object here is to give merely a general indication of the nature and scope of the problem in the South.

In former years, when physicians were not so well trained as they are now and when laboratory facilities were not available, the errors of diagnosis must have been greater than at present, but the reporting was less complete. There have been cases where health authorities have found, on investigation, that deaths had been erroneously reported as due to malaria. Dr. Bassett, the health officer of Savannah, Ga., for example, has since 1923 investigated every death ascribed to malaria but in which the parasites had not been found in the blood. He has reported on about 20 autopsies which failed to reveal malaria as the cause of death. Tuberculosis he found to be the usual cause of death in this group, and there were deaths due to pneumonia and cirrhosis of the liver, and one to typhoid fever. Whether the rate of error in the records as to the causes of death is greater for malaria than for other diseases, it is difficult to say, but it is probable that since well trained physicians and diagnostic laboratories are increasing in number, the rate of error is diminishing from year to year. Moreover, the reporting is much more complete. After all, since we have no substitute basis for the general measurement of malaria, we proceed upon the basis of death rates, and I repeat that, as indicators of trends, it is believed that these rates are dependable.

Herewith is presented a series of tables and graphs giving the mortality from malaria by years and states for which it was practicable to collect data. A study of the tables and the corresponding graphs will give a fairly good picture of the malaria trends of the past decade. A few comments on the more significant factors will be given.

MALARIA DEATHS U. S. REGISTRATION AREA, 1910-1928

The graph for the malaria death rates for the United States Registration Area and the supporting figures (Figure I and Table I) are misleading, certainly for the period 1910-1918, because during this period only 9 of the 16 states classed as malarious were in the registration area, and in 1910 out of 16 states incriminated in an article by

TABLE I

MALARIA DEATHS PER 100,000 POPULATION FOR THE REGISTRATION AREA, 1910-1928,
AND FOR NINE SOUTHERN STATES,¹ 1918-1929

¹ Alabama, Florida, Louisiana, Mississippi, Missouri, North Carolina, South Carolina, Tennessee, Texas.

Maxcy, to be referred to later, California was the only one within this area. The graph for 9 states shown also in Figure I is undoubtedly a more correct indication of the malaria trend for the included states. There seems to have been a low point in the mortality curve in 1915. Subsequently either the rate increased yearly up to 1919-1920, or the apparent rise was caused by the addition of malarious states to the registration area. In any case, the 1919-1920 period, whether shown by the registration area graph or by that for the 9 states, was a period of high mortality, and 1925-1926 a period of low mortality. By comparing these graphs with those for the individual states, the degree of similarity of the curves can be observed, as can also the extent to which the curves have risen during the past 3 years.

Before presenting data for the individual states, it would be well to call attention to the excellent article by Maxcy¹ in which he found the case fatality to be about 0.5 per cent. Maxcy arbitrarily designated as malarious all counties which, for a 3-year period, 1919-1921, averaged over 1 death per 10,000 population. A list of the malarious counties by states and the mortality rate for each county are included.

Some of his county figures are quoted in Table V-A. We take the liberty to present his summary as Table I-A to which, for convenience, we have added the columns showing the total number of counties and inhabitants of each state. It will be noted that Maxcy's study incriminated 12,662,256 inhabitants of 520 counties in 16 states, all of which, except California, are in the southern, central, and southeastern part of the United States. The areas involved in some states are quite limited. For example, there were only 4 counties in California, 9 in Illinois, 6 in Kentucky, 11 in Missouri, and 6 in Virginia. Oklahoma had 20, whereas Alabama, North Carolina, South Carolina, and Tennessee had a range from 25 to 30 counties, and the following states had more extensive areas involved: Arkansas 52 counties, Florida 41,

FIGURE I

MALARIA DEATHS PER 100,000 POPULATION FOR THE U. S. REGISTRATION AREA, 1910-1928, AND FOR NINE SOUTHERN STATES,¹ 1918-1929

* K. F. Maxcy's article on Malaria, U. S. P. H. S. Reprint No. 839, May 25, 1923.

Georgia 70, Louisiana 55, Mississippi 74, and Texas 64. The percentage of the population involved ranged from 1 per cent in California, 3 per cent in Virginia, 3 per cent in Illinois, 5 per cent in Kentucky, 6 per cent in Missouri, to 92 per cent in Mississippi, 80 per cent in Florida, 75 per cent in Arkansas and 71 per cent in Louisiana. Reference to Table V-A will show 14 counties for Florida (1927-1929 period), 7 for Alabama (1926-1928 period), and 22 for Georgia (1928), which on the 1 death per 10,000 population basis would be classified as malarious, although not present in Maxcy's list.

Virginia—The malaria of public health importance in Virginia is found in the southeastern counties. Maxcy's study incriminated only

¹ Number of deaths submitted by Dr. Grant, Director of Malaria Control, Virginia State Department of Health.

² Number of deaths submitted by the State Department of Health.

³ The counties are as follows: Accomac, Brunswick, Greensville, Henrico, Isle of Wight, Nansemond, Norfolk, Northampton, Princess Anne, and Southampton.

6 counties (6 per cent) and an area embracing only 74,355 inhabitants, or 3 per cent of the total population. The average number of malaria deaths annually he gave as 13. The mortality figures for the state since 1910 and for 10 southeastern counties since 1921 are given in Tables II and III and are graphically presented in Figures II and III. It will be noted that up to 1928 the mortality curve was downward, but that it went up sharply in 1929. It is singular that the low point occurred 2 years later than the low for the 9 southern states combined (Figure I).

North Carolina—The character of the malaria problem in North Carolina is suggested by Table IV and Figure IV. All 26 of the counties (26 per cent) classed as malarious are located in the eastern part of the state in the tidewater belt. About 24 per cent of the population of the state live in these counties. The graphs for the central or Piedmont area and that for the western or mountain area indicate that, except for the eastern section, malaria is not a serious public health problem. By reference to Figure III and the supporting Table III the extent of the disease in this state may be compared with that found in 5 other states. The position as to the mortality curve is intermediate between Virginia and South Carolina. This is true also as to the extent of the area involved and as to the rate of mortality in the groups of counties where the disease is important. For the state the mor-

tality curve dropped steadily from 1918 to 1927. In 1928 and 1929 the rise was perceptible but very slight. The low point occurred a year earlier than in Virginia and 2 years later than in South Carolina.

South Carolina—The mortality record for malaria in South Carolina is interesting. It will be noted from Table I-A that 26 eastern counties (57 per cent), embracing a population of 894,142, or 53 per cent, had an average of 233 malaria deaths yearly during the 1919-1921 period. The area involves approximately the eastern three-fifths of the state for the period mentioned. Figure III and Table III show that the mortality rose through 1922, then dropped sharply for 3

1928	2,397,411	13	0.5	3,048,051	64	2.1	1,722,796	382	22.2
1929	2,408,439	16	0.7	3,109,167	66	2.1	1,727,680	372	21.5

¹ Number of deaths submitted by the State Departments of Health.

years to 1925. During the succeeding 3 years there was a sharp and continuous rise, and a slight drop in 1929. The 1922 rate was 29.7, the 1925 rate 10.7, and the 1928 rate 22.2, a rise much greater than occurred in North Carolina or Virginia, but similar to that observed in Florida and Alabama. Dr. J. A. Hayne, State Health Officer, expressed the opinion that 1930 will show another rise.

Georgia—The mortality curve for the state (Figure IV-A) reached a high point (20.2) in 1922. During the next 3 years it dropped to 9.8 in 1925, where it remained to 1927; 1928 and 1929 showed marked increases. The curve of the rainfall throughout this period corresponds very closely with the mortality curve, the only discrepancy

being that the former was higher than the latter for 1926 (Figure IV-A). The mortality record for 1928 in 69 counties is compared in Table V-A with the mortality of these counties as reported by Maxcy for 1921. The 1928 list shows 22 counties which in the 1921 record were not included in the malarious class. The comparison of the mortality rate by counties in this table is interesting in that it shows by counties the fluctuation in the mortality rates. This, of course, is to be expected where small population groups are considered. According to Dr. T. F. Abercrombie, the State Health Officer, available data suggest that the mortality rate for 1930 for the state will be somewhat lower than for the previous year.

Florida—The malaria problem in Florida is extensive, severe, and difficult. Three-fourths of the counties, embracing 80 per cent of the population, are malarious. From a rate of 43.6 in 1919 for the state, there was a fluctuating reduction to 16.1 in 1927, with a sharp trend upward in 1928 and 1929 to 33.2 (Table V and Figure V). Table V-A compares the malaria rates for 41 counties incriminated by Maxcy for the 1919–1921 period with the 1927–1929 period and shows high rates for both periods, although in 25 of the counties the rates were lower in the later period.

Alabama—The malaria mortality record in Alabama is reflected in Table V and Figure V. In 1918 the state mortality rate was 16.3 and in 1929, 16.4. The curve from 1918 was generally downward

FIGURE III

¹ Number of deaths submitted by the State Departments of Health.

FIGURE IV

MALARIA DEATHS PER 100,000 POPULATION FOR THREE SECTIONS OF NORTH CAROLINA AND FOR THE STATE AS A WHOLE¹

¹ Figures submitted by State Department of Health, North Carolina.

until 1927 when the rate was 8.0. Of the 67 counties in the state, 29, or 43 per cent, including 37 per cent of the state population, were classed as malarious (Table I-A). Nineteen twenty-eight and 1929 were years of heavy precipitation and floods. Of the 29 counties which in 1919-1921 had over 10 deaths per 100,000 population, 18 continued to exceed this rate in the 1926-1928 period, and 7 other counties had increases which placed them in the malarious group, making a total of 25. The mortality curve for Florida for the past 8 years corresponds closely with those of South Carolina and Alabama and in all there were sharp rises in 1927 and 1928 with years of heavy rainfall in spring and summer.

Mississippi—Mississippi has had, and through 1928 continued to have, a serious malaria problem. In the 1919-1921 period (Table I-A) 90 per cent of the counties and 92 per cent of the population were in areas showing 10 or more deaths per 100,000 inhabitants. Figure III shows the state mortality curve and also compares the extent of its problem with that of 5 other states, 3 of them in the Mississippi River basin. In comparison with the curves shown for Tennessee and Kentucky, the Mississippi curve is high. Dr. Mark F. Boyd and his associates in the Mississippi State Board of Health have subdivided the 82 counties of the state into 5 groups and shown the malaria mortality rates and trends for each during the period 1914-1928 both for white and colored population (Tables VI and VII, and Figures VI and VII). For the state as a whole, 1921 was the record year for deaths, when the

rate was 53.1. The mortality curve then fell sharply to 19.4 in 1924. Thereupon it rose steadily for 4 years till it reached 28.1 in 1928. In 1929 there was a sharp drop which Dr. Boyd thinks has become even sharper in 1930, owing to the exceptional drought.

FIGURE IV-A

Tennessee—Malaria in Tennessee is found mainly in the western counties. The graph Figure III shows the trends in the death rates for the state as a whole for the period 1918–1929. The year 1921 was the high point in the mortality curve, when the rate was 15.2; and from the low point of 6.3, reached in 1925, there has been no increase to more than 7.0, except in 1928 when it was 8.3.

Kentucky—Kentucky, like Illinois and Tennessee, has only a small part of its area, 5 per cent of the counties and 5 per cent of the population, in the malaria zone. The general trend since 1918 (Figure III and Table III) has progressed downward from a rate of 4.7 to 1.4. The low point was reached in 1924. Except for the 3-year period 1926–1928, when it rose to 2.2, the rate has remained under 2.0.

FIGURE V

MALARIA DEATHS PER 100,000 POPULATION FOR SEVEN SOUTHERN STATES

NOTE—Arrow indicates year state was admitted to registration area, with the exception of Missouri, which was admitted 1911. Texas has not yet been admitted.

¹ Number of deaths submitted by the State Departments of Health.

Missouri—The trend of malaria mortality in Missouri for the period 1918–1929 is shown in Figure V. It has not fluctuated widely.

Arkansas—Malaria in Arkansas has been and continues to be a major health problem involving about 69 per cent of the counties in which about 75 per cent of the inhabitants reside. As in other states, the years 1921 and 1928 represent high points in the curve (Figure V), when the rates were 58.3 and 47.8 respectively. The intervening period showed only a slight drop, but that for 1929 is sharper.

Texas—Although Texas is not yet in the registration area, the record of deaths by years is available (Table V and Figure V). There will be noted a relatively high mortality for the 1915–1921 period, then a notable drop for 5 years to 1926, when the rate was 2.6. Since that time the rate has risen gradually but steadily through 1929 to 4.2. In

comparing the relative position of the various state mortality curves, we should again recall that certain groups of counties in a large state may present intensely malarious conditions while for obvious reasons the rate for the state as a whole will be low.

URBAN MALARIA—CHARLESTON, BIRMINGHAM, SAVANNAH, MEMPHIS

Malaria has been regarded in this country as essentially a rural disease. The studies of the past 10 or 15 years support this view. For the cities it is not easy to be sure how much of the malaria is contracted outside the city, but it is believed that in recent years the transmission within the cities, certainly within those having creditable health services, has been relatively slight. Dr. C. C. Bass supplied a record of the malaria cases in the New Orleans Charity Hospital for the period 1925 through October, 1930. There were 574 cases of which 287, or 50.0 per cent, were not residents of the city, and 30, or 5.2 per cent, not residents of Louisiana. According to Dr. Bass, deaths from malaria

are so rare in New Orleans that no definite opinion can be formed as to mortality. Only 4 deaths occurred in the total of 574 cases mentioned. In cities, the study of the age distribution of deaths and cases is important. Adults may contract the disease elsewhere, but in the case of children this is less likely. Table VIII and Figure VIII give the mortality curves for Charleston, Savannah, Birmingham, and Memphis. The record for Charleston includes the population of Charleston County as well as of the city, and it is presumed that deaths of non-residents are included. The figures for Savannah since 1923 are for city residents only. Those for Memphis presumably include all malaria deaths occurring in the city. As from one-fourth to one-half of the patients in a number of city hospitals are not residents of the city, the complete record of deaths may not correctly reflect conditions in the city.

MALARIA DEATHS PER 100,000 POPULATION FOR
FOUR SOUTHERN CITIES

CONCLUDING COMMENTS

During the 5-year period prior to 1920, there was general interest in malaria and in measures for its control. Studies designed to evaluate the various methods of control were undertaken by the U. S. Public Health Service and the state health departments, with the coöperation of the International Health Division of the Rockefeller Foundation. Drugs, screening, and drainage were tested under varying conditions. During the mobilization of troops for the Great War, a vast amount of control work about the cantonment areas, mainly by drainage, was carried on. Coöperative experimental drainage undertaken by the health authorities in the towns was so successful over a 3-year period

that in the last half of 1919 a program of coöperation between the U. S. Public Health Service and the state health departments—with the International Health Division of the Rockefeller Foundation participating—for extending the work to other malarious towns was instituted. This program was continued actively for 4 years during which 114 towns of 11 states were surveyed and anti-larval measures based mainly upon minor drainage were carried out.

In 1922 the extra-state agencies transferred their aid to programs involving state and county coöperation in measures for the control of

malaria in rural areas to county health organizations. As malaria had to take its place along with other health problems claiming the attention of the inadequately staffed organizations, and as the problem in rural areas is vast and far more difficult than in the circumscribed areas of the towns, the results have not been in the least spectacular. The declines in the death rates which occurred from 1922 to 1926 may have given a false sense of security and have tended to place unwarranted value on the antimalaria activities.

After a period of coöperation in both town and rural control measures, the outside agencies gradually reduced or withdrew their aid. To what extent the state and counties have increased or decreased their antimalaria activities, I cannot say. It is certain that with the marked rise in the incidence and death rates in 1927 and 1928, concern among the health officials was quite general and pronounced.

Field studies of malaria have been carried on more or less continuously in the South since 1915 by the official organizations aided by the coöperating voluntary health agencies. Knowledge as to the characteristics and habits of the 3 species of anopheles has been enlarged; the relative value of spleen, blood, and histories as bases for diagnoses and for indexes has been studied. Moreover, the conditions under which drainage, Paris green, screening, and the use of quinine or other drugs may be effective have been studied. To what extent the approach to malaria control has been influenced by the reports of these investigations is not known. It has been observed that the disease generally is more or less localized and that control measures must be aimed at the focuses of infection. In some localities, however, malaria is more or less widely and uniformly distributed. Certainly the enlarged knowledge should lead to more direct and more economical control measures.

The factors making for the general recession of malaria have not been convincingly evaluated. The extension of drainage and agriculture seems to have been related to the decline, but the influence of rainfall during the anopheles breeding season seems to be the most important single factor in the areas still classed as malarious.

The notable rise in the mortality curves for Florida and Alabama in 1929 to points higher than were recorded in the 1921-1922 peak (Figure V), and the somewhat more moderate rises in the other incriminated states make it clear that malaria is still a menace to the health and working efficiency of the people of the South, and that the measures directed against it were inadequate for holding the gains through wet years. Although the drought of 1930 may have again turned the general trend downward, this is not yet assured. Shall the

health forces let malaria have its way, or shall they influence its course and hasten its disappearance? The task offers a challenge.

We are still confronted with a disease about which we have had for years all knowledge regarded as essential, yet like another disease in this category—diphtheria—it is still with us. It thrives most in the type of community least able to combat it. Economic distress is associated with its rise either as a cause or as a result. When natural causes do not favor its recession, the health forces must redouble their activities and possess knowledge that will guide in the most direct and economical measures of control.

DISCUSSION

J. A. LEPRINCE

*Senior Sanitary Engineer, U. S. Public Health Service,
Memphis, Tenn.*

DR. FERRELL'S paper should arouse a wider interest in following the future trend of malaria prevalence. It certainly looks as though a change that we do not understand has taken place in parts of some states during the past 3 years. It has even been noticed in Illinois and southern Indiana. In the latter state the change was not due to local rainfall.

It is most unfortunate that information is available only for limited areas when there are malaria problems in 520 counties. Dr. Ferrell brings out the point that we have more complete reporting than we had in former years, and that is encouraging. I believe that it is possible for a larger number of county health units to get case records which would indicate more closely where the county malaria problems are, and that such information would be of value to the state health departments. It will be of interest to compare the reported case rates with death rates in county areas, to see the relative value of the two trends, when plotted with such data as are available, where the reporting is fairly complete.

Attention is called to the fact that since 1926 a start has been made toward the rural problem of malaria control and that we very much need more complete reporting by practising physicians in order to measure the results of anti-malaria activities over a period of years. The representative of the International Health Board in Mississippi has accomplished an outstanding piece of work in the delta counties of Mississippi this year and if we can have similar interest aroused in the malaria ridden counties of other states, we can get enough people to become interested in our problems to keep the trend of malaria where we want it. It is well worth while for the directors of county health units to make a strong effort to enlist the aid of the county medical society, and county physicians, in the reporting of all their malaria cases. Where this is not done they have no definite idea of where their problems lie.

It is my belief that the downward trend of malaria will be in direct proportion to the effort put forth on having the farm tenant population thoroughly understand

the need of their taking part in this reduction. We all realize the importance of having the carriers sleep in screened homes, and some county health departments have already shown that in years of average prosperity both plantation owners and tenants can be induced to pay for such protection in districts where other anti-malaria measures cannot yet be carried on. Such procedure is applicable to many localities where malaria is more or less widely distributed, and intensive study is needed to determine the best methods along this line, which can be made to increase the downward trend of malaria prevalence.

In Alabama, in September, 1928, 2,000 cases of malaria were recorded by physicians, in August, 1929, 2,879, and as this is only a portion of the cases that occurred among the rural population it is evident that we cannot afford to assume that our malaria problem is not worthy of attention.

V. M. EHLERS, C. E., F. A. P. H. A.

Chief Sanitary Engineer, State Department of Health, Austin, Tex.

OUR discussion of Dr. Ferrell's paper will relate only to conditions as they obtain in Texas. Exact statistics on the incidence of and deaths from malaria are not available. According to Dr. J. C. Anderson, State Health Officer, who practised years ago in central Texas, the bulk of his work 30 or even 20 years ago consisted in the treatment of malarial patients. A steady decline in the number of cases was noted up to about 10 years ago, which he believes was due to the efforts of physicians in educating the population as to the value of taking quinine, the screening of homes, and the destruction of mosquito breeding places as the country developed and farming conditions improved. Dr. Cumming, a prominent physician who has practised for many years at Hearne, in the malaria belt, concurs in Dr. Anderson's statements.

Surveys by Magoon and Hardenburg in 1919 and 1920 of a certain group of towns in east Texas showed 10 per cent to 35 per cent of the population affected with malaria. Surveys by Dr. William Sory in 1921 and 1922 in Cherokee County show a rate varying from 2.8 per cent in a town to 38.8 per cent in a rural district.

Records of the Cotton Belt Railway show a decline in the number of cases noted among their employees at the beginning of their control work in 1917. The 1913-1916 average showed 602 hospital cases per year from about 6,600 employees and the 1928-1929 average showed 68 hospital cases per year among approximately 6,000. Malaria deaths reported to the State Department of Health over a 20-year period declined from 407 in 1910 to 238 in 1929, with the lowest figure at 139 in 1926. The malaria death curve graphically shows a steady decline up to the last 4 years. Records of cases are not available except for the past 4 years. For that period the total cases reported for the state were: 12,542 in 1926; 8,823 in 1927; 13,623 in 1928; and 15,697 in 1929. It is estimated, however, that only about 40 per cent of the cases are reported; hence, we have at least 50,000 cases annually in Texas. According to the estimates of 1928, the population of the 108 counties affected was 3,266,000. For the 4-year period named the rates in consecutive order are 380, 239, 417, and 480—or an increase of more than 100 cases per 100,000 in 1929 over 1926.

In order to study the relation of the rainfall of the section to the incidence of

malaria, data on the average precipitation for the 4-year period were compiled. Figures from the U. S. Weather Bureau showed an annual precipitation of about 49.7 inches in 1926; 43.7 in 1927; 38.7 in 1928; and 44.1 in 1929. The lowest figure is for 1928, whereas the lowest number of malaria cases was reported in 1927. From this very limited comparison, we would say that the variation in rainfall apparently had no effect upon the number of cases reported.

We made a further selection of a group of 11 counties which showed the highest incidence of malaria according to physicians' reports for the 4-year period and determined the case rates by the estimated population of 1928. See Table I for a tabulation of these figures.

TABLE I

County	Population	Rate per 100,000 (Av. for 4 yrs.)
Morris	10,298	3,175.0
Red River	35,829	1,102.0
Nacogdoches	28,457	1,049.0
Lamar	55,742	1,011.0
Kaufman	41,276	940.0
Fannin	48,186	940.0
Hunt	50,350	810.3
Collin	52,000	669.0
Cameron	65,000	444.6
Wichita	115,000	362.0 (For 1929 only)
Hidalgo	75,000	344.0

Wichita County is included in this group, although it is well beyond what is ordinarily termed the malaria belt of Texas. Irrigation was introduced in Wichita County on rather a large scale in 1926. In 1926, 3 cases of malaria were reported, 31 in 1927, 9 in 1928, and 417 in 1929—a rate of 362 per 100,000 population as indicated above. The high incidence in Hidalgo and Cameron counties may likewise be attributed to the effect of irrigation. Each year sees more land irrigated—and a greater incidence of malaria. Referring again to Cherokee County, in 1919 the town of Jacksonville reported over 800 cases of malaria, which after persistent control work declined to 7 in 1929. Other towns which have carried on control work year after year show a decline. A low level has been reached which never rises to that of 20 years ago. Intensive work is being carried on in about 40 towns at present, while possibly 100 or more do some work of an intermittent nature.

The State Department of Health is asking for an appropriation for malaria control work for the coming biennium. If granted, the money will be expended in employing county sanitarians or "mosquitoologists," and the establishment of county units in the malarial sections. An educational campaign put on recently by the department had the active support of the East Texas Chamber of Commerce. Through addresses made before a population of some 25,000 persons in the 40 towns visited, an attempt was made to arouse interest in the problem. The enormous economic losses were recounted and compared with the cost of control. It is hoped to continue educational work through the spring and summer, and, if possible, induce all counties affected to carry the work into the rural communities.

In the opinion of our epidemiologist and others conversant with conditions, malaria in Texas is now primarily a rural problem. It has reached as low a level as is possible without further intensive work which should be extended to the rural districts on a widespread basis.

FELIX J. UNDERWOOD, M. D.

State Health Commissioner, Jackson, Miss.

IN 7 months, January to July, 1930, there were reported 122 deaths ascribed to malaria as against 118 in same period of 1929. In each year there were reported 46 deaths in whites during the same period. Of the white deaths in 1929, the diagnosis in only 2 was reported as having been verified by microscopical examination, against 11 in 1930. In none of the 1929 negro deaths had the diagnosis been verified, while in 1930, 5 were. It would appear that some progress is being made in the more precise diagnosis of malaria.

For the period considered, the mortality reports do not indicate a significant difference in the incidence of malaria in 1929 and 1930. It is the present belief, however, based on diagnostic laboratory examinations, the results of field surveys, and data gathered from practising physicians, that in our delta territory the incidence of malaria in 1930 is lower than in 1929, and perhaps is the lowest on record. This is attributable to the severe drought.

The malaria control program in Mississippi is executed by and through the whole-time county health departments and is largely directed to the rural problem. It has been developed with a full appreciation of the meager resources and varied responsibilities of these organizations. It is realized that the accomplishments of any one year can only be modest in extent, and that satisfactory results require sustained, uniform efforts over an extended period. The supervision of the State Board of Health should guarantee the continuity of this program.

In brief the program is:

1. Education of physicians to be more precise in making a diagnosis of malaria, and requirement of the reporting of cases individually with particulars regarding place of residence. The health departments are required to keep spot maps of these cases.

2. Popular education, carried on largely through the movies, some of which is particularly designed to reach the negro.

3. The promotion of screening.

4. The promotion of minor drainage.

The first year's operation has demonstrated the workability of this program, while in several counties very satisfactory progress has been made.

OUTLOOK FOR 1931

We regard the situation in 1931 with concern. It is desirable to conserve to the greatest extent possible the natural gains of 1930, yet the current economic depression will probably make it difficult to accomplish as much.

Cost of Malaria Control*

J. A. LePRINCE

Senior Sanitary Engineer, U. S. Public Health Service, Memphis, Tenn.

COST of malaria control includes medical treatment and preventive measures such as larval control of anopheles, screening of houses, use of mosquito bars over beds and destruction of anopheles in homes.

In towns and villages where larval control is being accomplished it is generally the desire of the public that the work be done in such a manner that not only shall there be a reduction of malaria but also a most decided reduction of pestiferous mosquitoes. In most instances as the campaign advances it obtains approval or disapproval according to the prevalence or absence of non-disease bearing mosquitoes, and this condition has often compelled the field workers to undertake the elimination of *stegomyia*, *Culex fatigans*, and other mosquitoes, as well as *Anopheles punctipennis*. We have communities where several times as much is being spent for control of *Anopheles punctipennis* as for reducing the prevalence of *Anopheles quadrimaculatus* and treatment is given to stream beds where it is known that no *quadrimaculatus* are produced. Frequently it is not practical to separate the cost of anopheles control from that of general mosquito control, and therefore the cost of the latter is given as that of anopheles control, although at times it is several times more than what the cost of eliminating *Anopheles quadrimaculatus* would be.

In 1913 and 1914 the field working parties of the U. S. Public Health Service found that in Georgia, North Carolina and South Carolina when the *Anopheles quadrimaculatus* was not present there was very little or no history of transmission of malaria, though in some of the communities studied imported malaria carriers were present and *Anopheles punctipennis* were very numerous. This species was decidedly annoying to persons on porches after dusk but did not appear to frequent inhabited houses, though frequently found in the daytime in outhouses and unoccupied houses as well as under occupied homes raised from the ground.

The spending of millions of dollars annually for mosquito wire

* Read before the Public Health Engineering Section of the American Public Health Association at the Fifty-ninth Annual Meeting at Fort Worth, Tex., October 28, 1930.

screen seems to indicate that the public desire mosquito freedom and think more of that than of freedom from malaria. It is not unusual to find a large portion of the homes screened where no malaria exists and very few screened where malaria prevalence is unusually high.

During 1920, 45 towns and villages initiated malaria control campaigns. The cost per capita for anti-larval measures varied from \$.42 to \$2.52, and averaged \$.80. During 1921, 26 other towns initiated similar campaigns and the cost per capita averaged \$.72. These costs are from towns of 10 southern states for the first year's work and naturally include considerable installation of new ditches. The cost of maintenance the second year and thereafter will run about one-quarter to one-third of that of the first year. The anti-larval measures refer to ditching, maintenance of ditches, and application of larvicides, and the costs are of mosquito control not of *Anopheles quadrimaculatus* only.

In tropical countries having heavy rainfall, long rainy seasons and clay soils, the cost of larval control is relatively high and application of oil is unusually high because of interference of oil spread by quick growing vegetation.

While the Panama Canal was being constructed the cost of mosquito control activities, exclusive of screening homes, was approximately \$.01 per capita per day. Of course, that meant operating about 300 days each year, while in the greater part of our malaria belt here the mosquito control period is only about 130 working days for the anopheles season. The annual rainfall at Panama is from 60 to 180 inches per year according to location. In our short anopheles season here we often have dry periods with less anopheles breeding area.

A cost of \$3.65 per capita per year may seem high, but is actually relatively low as compared to average loss of wages when more than three-quarters of the people are suffering from malaria where preventive measures are not undertaken.

It is not generally known that millions of dollars are being spent in our southern states for the prevention of malaria by agencies developing hydro-electric power. Some of the artificial lakes being formed in our river valleys have shore lines varying from 12 to several hundred miles in length. Clearing of brush and trees from some of the larger projects to prevent anopheles production is decidedly expensive and exceeds $\frac{1}{4}$ million dollars for a single project. Where there are but 200 families within anopheles flight range of a lake that costs \$100,000 to clear, the cost per family for protection from malaria is \$500. In the *Southern Medical Journal*, May, 1930, Dr. L. T. Coggeshall reported that Lake Murray, being constructed near Columbia, S. C., will have an area of 75 square miles, a shore line of about 540

miles, and the cost of clearing will approximate $2\frac{1}{2}$ million dollars. The annual interest on this sum is probably more than all state health departments are able to obtain to apply to malaria elimination.

With the discovery and use of Paris green as a larvicide for *Anopheles quadrimaculatus* we have a new condition—a larvicide that does not destroy the larvae of pestiferous mosquitoes, but which will often enable us to control anopheles at possibly one-quarter of the cost of destruction of all types of mosquito larvae. When there is much aquatic growth, brush, and floating débris present, we cannot always control anopheles production areas effectively and economically by the use of oil, but when we use Paris green mixed with hydrated lime such obstructions in no way interfere with dusting operations; so we have a quicker, cheaper and better means of control than formerly. In other countries this cheaper method is being widely used while with us, where the method originated from investigations of the U. S. Public Health Service, it is not yet in common use.

During 1929 Dougherty County (Ga.) Board of Health dusted with Paris green at 10-day intervals all *Anopheles quadrimaculatus* breeding areas in Dougherty County. The cost was \$7,957, and the area of the county was 343 square miles. The cost per acre per season was \$.036. In studies made in Tennessee it was found that in a stagnant stream bed about 5 feet wide, a man with a hand dust gun carrying a charge of 10 lb. of Paris green mixture could cover from 3,000 to 4,000 linear feet of stream bed per hour, depending on variation of air currents.

During this operation it was necessary for the operator to cross the stream a number of times because of the changing direction of the axis of the stream bed with respect to the prevailing direction of the wind. In dusting large areas throughout the anopheles season there will be considerable variation of cost depending on the amount and frequency of rainfall. In county-wide dusting operations to date, the cost for labor and Paris green mixture for the entire territory (wet and dry included) varied from $\frac{1}{3}$ to $\frac{1}{2}$ cent per acre per dusting, but of course this cost may vary more widely according to the extent of wet area of any county that is suitable for *Anopheles quadrimaculatus* production.

In some states and counties we find malaria prevalent in sparsely settled rural districts. Where the income of such counties is small and the counties are not yet ready to undertake larval control as a malaria control measure, screening of farm homes and of farm tenant homes should be considered. During the summer of 1927 the Red Cross and the U. S. Public Health Service screened about 8,000 farm tenant homes in the flood area of the Mississippi River in 4 states. The average cost was \$10 per home. In the counties of Mississippi there was

an average of 3-and-a-fraction screen doors per home. As this malaria protection measure lasts for from 4 to 5 seasons, and even longer where the screen is painted, the cost per year averages from \$2 to \$2.50 per family per year for the first 5 years. As reinforced doors are used they last a long time, and those installed in 1922 are as good as when first installed. For an average family of 5 this cost becomes about \$.50 per person per year.

Eight county health officers have already undertaken screening campaigns and one of them visited the hardware dealers of his county to find out whether his activities were decreasing the sale of screening by hardware dealers. He was told that since his campaign got under way from two to three times the normal amount of window screen and screen doors had been called for. It has also been noticed that where county-wide screening campaigns are undertaken a considerable number of tenants and owners build their own screen doors, and then the cost per capita per year is considerably reduced, as this work is done in spare time. Where tenants buy and use the cheapest type of screen door they can get, they should be advised to reinforce doors on both sides with 22 gauge galvanized iron, 6 inch right triangles in order to double the life of the doors.

In some of the counties having the highest malaria prevalence a large portion of the farm tenant families are spending almost as much for bed mosquito bars as it would cost to keep the house effectively mosquito proof. Most of these bed nets have holes in them. Many sanitarians, as well as these people, are unaware that a mosquito bar is a preferential resting place for anopheles and that more than half of the people who sleep under bed nets are bitten while they are asleep when they come into contact with the cotton mesh. Of all measures used by the American public for malaria control the use of bed nets is the poorest and probably the most expensive considering the small benefit actually received.

It does not take long to persuade colored farm tenants to care for the screen protection on their homes. It is essential to do so. In one of the Mississippi River counties the owner of the largest cotton plantation area states that the screening of his colored farm tenant homes and keeping them screened is the best investment he ever made.

It is unfortunate that we have the greatest proportion of unscreened homes in rural areas having the highest malaria rates, and the property owners do not yet realize that unseen taxes are collected from them which greatly exceed the cost of screening of farm tenant homes. County health workers will find that it is in this type of home that we have most sickness and most fly-borne disease.

Screening and Mosquito Proofing as Elements in Malaria Control*

HOWARD R. FULLERTON, C. E.

Tennessee State Department of Public Health, Nashville, Tenn.

THE Tennessee State Health Department program is essentially a county health department program. With this in mind, our county-wide malaria control programs have been built up around the full-time county health departments, and the malaria program has been made an active part of their work and sponsored locally by them. The local health departments do not do malaria control work exclusively, but carry it along as one of their major activities in their general health work. There are 9 full-time county health departments in that section of the state in which malaria is of public health significance, 5 of them located in the counties having the highest malaria morbidity and mortality.

The principal malaria control problem lies in the western third of the state between the Tennessee River, which traverses the entire width of the state, and the Mississippi, our western boundary. This area is approximately 100 miles long and 100 miles wide, mostly flat, with many low hill sections. Streams are sluggish, and there are many places for mosquitoes to breed in easy flight range of most of the houses. In this section the Tennessee Department of Public Health has concentrated its major malaria control activities. Screening and other mosquito proofing of houses have been the major activities. These are important methods of malaria control, particularly where other methods of county-wide control are not economically feasible, or have not been developed far enough to demonstrate that they will insure fair results for money spent.

Screening alone must not be confused with mosquito proofing. In a large percentage of tenants' homes in Tennessee screening of the doors and windows is only part of the job of preventing the ingress of anopheles. Carpenter work is often necessary, floor cracks have to be stopped up or covered, walls papered to cover cracks or holes, naphthalene put into the chimneys and other work done. In addition, inten-

* Read before the Public Health Engineering Section of the American Public Health Association at the Fifty-ninth Annual Meeting at Fort Worth, Tex., October 28, 1930.

sive educational programs are carried on emphasizing the proper use and care of the screens as well as general malaria prevention.

Three municipalities have recently passed city-wide house screening and mosquito control ordinances: Memphis, Humboldt, and Milan, with populations of 252,000, 4,500 and 3,500, respectively. Memphis at present has one of its best sanitary officers devoting his full time to this work. He has the advantage of the previous experiences of the Shelby County Health Department in methods of promotion, measuring for screening, making and hanging screen doors, and observing the various other methods of mosquito proofing.

Before we advocate a screening program, a careful study is made of the malaria incidence. This is usually a combination of case histories, blood indexes of school children, both white and colored, and spleen examinations.

The first screening in Tennessee was done in Lake, Shelby, Dyer and Lauderdale Counties, by the American Red Cross, in 1927, after the big Mississippi River flood of that year. At present, Lake, Shelby and Gibson Counties have county-wide screening programs. Because the financing and general procedure in each of the 3 counties is quite different, it will be of interest to discuss briefly each of the plans.

LAKE COUNTY MOSQUITO PROOFING PROGRAM

Lake County is low and flat and lies between Reelfoot Lake and the Mississippi River. The county is traversed with sloughs, and almost every house is within flight range of a *quadrifasciatus* breeding place. Cotton is the chief crop, and there are only two towns in the county, neither of which is over 1,200 in population. The population is of the tenant-farmer type and some 12 land owners control or own possibly 80 per cent of the land.

Early in 1928 the larger land owners were invited to a meeting, which included several county officials. A county antimalaria committee was formed, consisting of 5 principal land owners, 1 from each section of the county. This committee provided a revolving fund of \$600 and secured from hardware and lumber firms a 90-day credit allowance, equivalent to approximately \$2,000, total assets to be used by the committee for the manufacture of screen doors. Excellent factory quarters were obtained free of charge, and equipment used by the Red Cross in 1927 was installed.

The doors were patterned exactly in accordance with the design of the U. S. Public Health Service. A door identification card was developed, also other forms for adequate house surveys to show sizes and direction of swing of doors, sizes of windows, and other data. At

present, approximately 90 per cent of the county has been screened.

One large land owner gave us to understand, early in the campaign, that she would never do any screening. We screened all around her property, and when tenants began to move to other places where mosquito proofing was available, she changed her mind. Needless to say, her own house was completely screened with 16-mesh wire.

For mosquito proofing the walls and ceilings, we have utilized used cotton sample paper. This is very tough and heavy, difficult to tear, and is used to wrap up cotton samples for shipping. Thousands of pounds of this are received in Memphis yearly, and not used again. However, local junk dealers buy all of this paper possible; hence, we have keen competition in securing it. We secured many tons free from philanthropically inclined cotton dealers, and later through the endorsement of the Memphis Cotton Exchange we were given all paper from each member firm except one.

The paper is 4 ft. wide and comes in varying lengths, from 2 to about 15 ft. The enormous amount required to paper an entire county is indicated by the fact that at one time, in Lake County, we had enough paper to cover a wall 8 ft. high and 13 miles long.

Shelby County Health Department collects the paper by truck on regular schedule; at some places every day, at some every other day, and at others not so frequently. It is then rerolled in small bundles, which reduces waste and enables the distributor to leave more nearly

TABLE I. POUNDS OF PAPER FOR ROOMS. *Cotton Sample Paper Only*

A table is used showing amounts of paper necessary in pounds for various sized rooms, varying in height from 7 to 10 ft., inclusive, in width from 6 to 18 ft., inclusive, and in length from 6 to 18 ft., inclusive (see Table I). With this table, a sanitary inspector can tell at a glance, after measuring up the room, exactly the amount of paper needed, put it down on his survey sheet in the field, and not have a mass of calculating to do in the office. A "tack factor" is also given on the paper table, so that the amount of tacks needed can be immediately determined.

In Lake County, we believe we have the first county in the United States with county-wide house numbering. The county is divided into 8 districts and the houses in each are numbered serially. The first digit in each house number is the number of the civil district in which the house is located. This method enables one to know at once the exact location of each house. The house locations were spotted on maps, so that the health officer, nurse, or sanitary officer can easily find them. This system enables the numbering to be carried on satisfactorily as new houses are built in each district, and not have perchance a very large number alongside of a small one.

This is the only method by which houses can be positively identified from year to year, where there is a large tenant turnover. For example, where there are 20 houses scattered over a farm and the tenants change houses or new ones come in, there is no other method of identification that is so accurate as numbering. Numbering is of distinct value to the health officer with regard to other activities, such as locating cases of communicable disease. He, or any member of his staff, can go directly to a house and not spend a long time in finding the place in which a call of a few minutes is to be made. It also aids in mapping locations of satisfactory water supplies and sanitary privies.

I would like to refer particularly to the cost of numbering the houses in Lake County. The numbers were hand-stamped on galvanized sheet iron plates 1" x 3" by a sanitary officer. The sheet iron was waste, secured free from furnace and tin repair shops, and later cut to the desired size. The numbers were stamped on the metal with steel number punches, each figure being $\frac{1}{2}$ inch high. The set of number punches (0 to 9, inclusive) cost \$3.50. The numbers were nailed on the houses directly over the front door, or near the top of it, with a nail in each end of the plate to make removal difficult. Exclusive of the time of the sanitary officer, during which he was incidentally engaged in a general house-to-house survey, it is estimated that the total cost of the county-wide house numbering has been not more than \$10.

Each lumber dealer and hardware merchant was interviewed in regard to making and selling the U. S. Public Health Service type of door. Most of the hardware men had friends who were lumber dealers who would make screen doors for them at a price which would allow them a profit. A meeting of all dealers was held and \$2.25 per door agreed upon. The dealers also agreed not to sell any more screen wire with a mesh larger than 16 to the inch after the stocks on hand were exhausted. Several of them had been selling only 16-mesh wire for a long time. The County Health Department agreed to do all of the propaganda work through the newspapers, and the State Department of Health loaned its journalist to write articles concerning the program and the particular type of screening. These were distributed regularly to each newspaper in the county.

The towns of Humboldt and Milan both passed home mosquito proofing ordinances as well as the standard mosquito ordinance of the U. S. Public Health Service declaring it a nuisance to raise mosquitoes on private premises.

There are 8 incorporated towns in Gibson County, so distributed geographically that citizens can secure U. S. Public Health Service type screen doors and 16-mesh wire from their local dealers in any section of the county.

SHELBY COUNTY MOSQUITO PROOFING PROGRAM

Memphis is located in Shelby County. There is a densely populated district adjoining the city on three sides. The county is largely composed of low lying hills, bordered on the west by the Mississippi River and traversed by two fair sized rivers and a number of creeks. Cotton and corn are the principal crops. There are many small communities scattered throughout the county.

The county-wide screening campaign was started by the organization of an antimalaria committee with an active general chairman who is vested with power to act in accepting contracts, paying bills, and in the general conduct of the screening. The county commissioners gave \$1,000 for a revolving fund and, in addition, furnished trucks free of charge for the transportation of screen doors and screen wire, collection and distribution of paper, and for other materials and labor.

One reason for the success of screening in Shelby County is that all of the sanitary officers were put through a rigid training in screening. They were taken into the field and taught how to measure doors and windows. Afterward, they went into the shops and actually made the doors and then hung them, and screened the windows. In this course of training they were taught to measure up and inspect screening;

hence their efficiency in screening promotion work was very much improved. When they were sent out to sell screening, they were able to tell about it intelligently because they had done it themselves.

OTHER WORK SUPPLEMENTARY TO SCREENING

The Tennessee Department of Public Health has an all around balanced malaria control program. In addition to screening and often supplementary to it, it is carrying on active programs in:

- Impounded water control
- Municipal mosquito control
- Consultant service to city and county health officers on special malaria control problems
- Combined land reclamation and mosquito control
- Plasmochin demonstration and studies
- Schoolchild surveys in spring and fall for malaria in certain counties
- Paris green dusting
- Roadside borrow pit control
- 1. State Highways:
 - By clause in State Highway specifications, requiring proper drainage of all borrow pits along state highways.
 - By a definite contract, the State Highway Department is now draining borrow pits along state highways left undrained before establishing the drainage clause.
- 2. County Highways:
 - Similar programs are being worked out for county roads.

Pasteurization of Milk

EXPERIENCE has shown that where pasteurization (the heating of milk under conditions which insure the destruction of harmful bacteria, yet leave the vitamins unimpaired) is generally practised, infection traceable to milk recedes almost to vanishing point. This fact has led no fewer than 21 cities in the United States to ordain the compulsory pasteurization of milk.

The signatories, while expressing no opinion on the principle of compulsion, are emphatically agreed that the time has arrived when, in order to increase milk consumption and diminish the risk of milk infection, pasteurization should be universally recognized as the immediate practical method of insuring safety. They record their satisfaction at the fact that about 90 per cent of the London supply is pasteurized with markedly beneficial results.

They are of the opinion that the first step in educating the public to demand pasteurized milk should be the simplification of the present milk grading system and the clear labelling of pasteurized milk as such. They are further of opinion that while no effort should be relaxed to improve milk at the source, the entire milk-supply—excepting "Certified milk"—should be pasteurized.—From Letter to Editor of *The Lancet* from Lord Dawson of Penn and others, Dec. 13, 1930.

The Olean City Epidemic of Typhoid Fever in 1928*

ARCHIBALD S. DEAN, M. D., DR. P. H., F. A. P. H. A.

*District State Health Officer, New York State Department of Health,
Buffalo, N. Y.*

(Formerly of Jamestown, N. Y.)

AN epidemic of 248 cases of typhoid fever occurred at Olean, N. Y., in the fall of 1928. This was due to a break in the submerged suction pipeline from a well in the Allegheny River and insufficient chlorination of the water supplied to the city. Of the total number of persons infected, 214 were residents of Olean City. Of the remainder 18 were from Cattaraugus County, 9 from elsewhere in New York State, 6 from the adjoining State of Pennsylvania, and 1 from West Virginia. The case incidence for the residents of Olean City, with an estimated population of 21,599 in 1928, was almost exactly 1 per cent of the population. There were 25 deaths, including 20 residents of Olean City, giving a 10.1 per cent fatality rate for the total cases.

The investigation and management of the typhoid epidemic during October and November, 1928, were under the supervision at Olean of Dr. B. E. Roberts, State Epidemiologist. The annual report of the New York State Department of Health for 1928¹ records the epidemiological features of the outbreak which was easily shown to be water-borne.

City water was used by all the persons affected and there was no other factor common to a significant proportion of the cases. There were in Olean over 1,000 cases of gastroenteritis in January and February, 1928, and over 5,000 during the latter half of August and the first half of September, prior to the onset of most of the typhoid fever.

The water supply of Olean was derived from two sources, Olean Creek and South Olean wells. Olean Creek water, which was filtered, chlorinated, and pumped into the distribution system at North Olean, was found by daily tests to contain residual chlorine and to be free from *B. coli*. The auxiliary South Olean well supply came from 12 or more 6" and 8" tubular wells sunk about 72' deep in the low ground

* Read before the Epidemiology Section of the American Public Health Association at the Fifty-ninth Annual Meeting at Fort Worth, Tex., October 27, 1930.

on the north side of the Allegheny River and from a large open collection and suction well on the south bank of the river. Two of the tubular wells had become submerged within recent years by changes in the course of the river. Water from these wells passed by screw-joint iron suction pipes across the river bed to the collection and suction well. After chlorination, instituted by a device which operated by remote control when the electric pump was started, the water was forced into the distribution system. Raw sewage from nearly half the city entered the river and its tributary above the wells.

On September 8, 1928, a man heard a suction noise in the vicinity of one of the submerged wells and reported it to the city water department. On September 10 the suction pipe leading from a submerged well was found to be broken and the well was cut out. Early in the morning of September 13 the use of water from the South Olean wells was discontinued for all time.

There was failure to make daily or regular tests of the South Olean water for residual chlorine, so additional chlorine was not added to take care of the polluted river water. Nine of 16 South Olean water samples examined at the city water department laboratory in July, August, and September, gave presumptive tests for *B. coli*, and a sample of water taken on September 13 at the Cattaraugus County Laboratory in Olean contained confirmed *B. coli*.

The typhoid epidemic cases were concentrated more than the population in the southern and central parts of Olean, which were supplied most directly with South Olean well water.

FIGURE I—Tubular Well in Allegheny River

FIGURE II—Sewer Outlet at Allegheny River

DATES OF FIRST SYMPTOMS OF TYPHOID FEVER

The dates of first symptoms of typhoid fever for the 248 patients, including 8 known secondary cases, are shown by the accompanying histogram (Figure III). Ninety-seven per cent of the onset dates for the primary cases from August 21 to December 8, 1928, were in Sep-

tember and October, including 74 per cent in September. There were 18 cases with onsets on each of 3 days, September 23, 27, and 30. One hundred twenty-eight patients or more than half the total had first symptoms during the 9 days September 23 to October 1, for which September 27 is the mid-date.

FIGURE III

Dates of First Symptoms of Olean Epidemic Typhoid Cases
August 21 to December 9, 1928

TABLE II

Epidemic	Number of Cases Used	Incubation Period in Days	
		Mean	Range
Mankato, Minn., in 1908.....	21	13.81	5-29
Excursion steamer reported by Lumsden in 1912.....	13	19.38	7-38
Old Salem Chautauqua reported by Feiguson in 1916...	181	19.50	7-40

There was one visitor to Olean on August 11 and there were 7 from September 8 to 12, inclusive, for from 1 to 3 days, who later developed typhoid fever (Table I). Assuming that infection occurred on the mid-day, the mean incubation period was 16.4 days and the range was from 4 to 29.5 days.

As noted previously, the mid-date for the most of the typhoid cases was September 27. This was 17 days after the removal of the defective pipe in the Allegheny River.

The mean incubation periods for other water-borne typhoid epidemics are given by Miner in Table II.²

The 8 Olean typhoid cases had a mean incubation period midway

between that for the Mankato patients and the periods for the individuals in the other two epidemics.

Sex—There were 18 more males than females among the 248 persons who had typhoid fever, including an excess of 12 males in the list of 34 patients who were not residents of Olean City. The percentage of males for the Olean residents was 51.4 and for the non-residents 67.6.

Age—The ages of the 248 patients ranged from a female contact case 18 months old and a female primary case 34 months old, to a male primary case 74 years of age. There were 11 children, including 7 males, under 5 years of age, 19 more 5 to 9 years and 12 persons of 55 years and over. The remaining 206, or 83 per cent of the total, were age 10 to 54 years.

All who had typhoid fever were white persons except for a male negro, age 54 years. According to the state census in 1925 there were in Olean 229 colored persons.

TABLE IV
TYPHOID ATTACK RATES FOR OLEAN CITY RESIDENTS BY AGE GROUPS

Age Group	Population *	Typhoid Cases among Olean City Residents	
		Number	Per 1,000 Population
Under 5	2,264	8	3.5
5-9	2,070	18	8.7
10-14	1,962	29	14.0
15-19	1,789	28	15.6
20-24	1,962	24	12.2
25-29	1,919	20	10.4
30-34	1,789	21	11.7
35-39	1,682	15	8.9
40-44	1,358	13	9.5
45-54	2,221	27	12.2
55-64	1,552	6	3.9
65 and over	991	5	5.0
Total	21,559	214	9.9

* Population of Olean City July 1, 1928, is based on 1920 and 1930 federal censuses.

Among the Olean City residents the typhoid attack rate was relatively low in the age groups under 5 years and 55 years and over, and high in the age groups 10 to 34 years and 45 to 54 years.

The case fatality rate for the patients under 20 years of age was 9.9, for those ages 20 to 44 years 7.8, and those age 45 years and over 15.8. The males under 20 years of age had a fatality rate of 6.7 in comparison with one of 13.0 for the females, and the males age 20 to

44 years a rate of 4.5 to one of 12.2 for the females. The males age 45 years and over on the other hand had a case fatality rate of 27.3 compared with a figure of only 5.0 for the females (Table V).

The mean length of life after the first symptoms of typhoid fever for the 25 patients who died was 29 days. The 12 males lived, on an average, 5 days longer than the 13 females. The shortest period of illness resulting in death was 9 days and the longest 52 days (Table VI).

Laboratory records of 2,497 specimens obtained from 234 Olean typhoid patients during and after their illnesses are shown in Table VII.

The 248 typhoid cases have been classified by laboratory test results. The blood agglutination test was extensively used to confirm the diagnosis. The isolation of the typhoid bacillus from feces and urine was generally attempted only for the purpose of determining carriers. Less than 30 days after the onset of illness the blood Widal was reported positive for 165 individuals and partial for 12 more, but *B. typhosus* was isolated from the feces of only 17 and from the urine of but 3 persons.

In all, the blood widal was positive for 171 individuals, including 22 who had previously had typhoid vaccine, partial for 14 more, including 2 who had received the vaccine, negative for 13, including 2 who recently had been given typhoid vaccine, and not known for 50, of whom 5 died.

The mean length of time after the onset of illness, as stated on the record sheets, that the Widal was discovered to be positive for 149 persons who had never had typhoid vaccine was 13 days. The median was 11 days, the mode 6 days, and the range 2 to 93 days.

For 6 patients without typhoid vaccine the Widal on an average was negative 8.5 days and positive 13 days after the onset of illness; for 8 more the Widal was partial 14 days and positive 17 days after the first symptoms of typhoid fever.

TYPHOID CARRIERS PRESENT BY MONTHS

The duration of the persistence of typhoid bacilli in both the feces and urine or in one or the other has been determined for 211 patients for whom there were release specimens. All the 248 typhoid cases were included except the 25 who died and 12 who lived away from Olean and submitted no release specimens.

Typhoid bacilli were found in the feces or urine of 88 of the 211 persons at some time. The total number of typhoid carriers at the end of the first month after the onset of illness was 78, assuming that

individuals who were found in later months to be excreting typhoid bacilli did the same earlier. At the close of the third month there were 24 carriers, or 11.4 per cent of the 211 individuals for whom there were release specimens. After 5 months there were no persons who excreted typhoid bacilli in the urine alone.

The number of typhoid carriers at the end of 6 months was 14, or 6.6 per cent of the patients examined, and at the close of 8 months was 12, or 5.7 per cent. The latter 12 have remained typhoid carriers for over 16 months, or as long as tests have been made.

Typhoid bacilli were found in the feces of 63 of the 211 persons at some time. The number of fecal typhoid carriers at the end of the first month after the onset of illness was 55 and at the close of the third month was 20, or 9.5 per cent of the persons examined. After the fifth month the numbers of fecal typhoid carriers were the same as those given in the preceding tabulation for fecal and urinary carriers.

Typhoid bacilli were discovered in the urine of 53 persons. The number of urinary carriers at the end of the first month after the onset of illness was 51 and at the close of the third month was 18, or 8.6 per cent of the 209 individuals for whom there were release specimens. One month later there were 13, or 6.2 per cent. At the termination of 5 months the urinary carriers numbered 9, or 4.3 per cent of the persons examined. The typhoid bacilli were found in the urine of 10 of the 12 chronic fecal typhoid carriers more than 4 months after the first symptoms of typhoid fever.

There were 51 individuals, including 29 males, whose stools contained typhoid bacilli and then became negative. The median number of days after the onset of illness that *B. typhosus* was last present was 44, and first absent for two or more consecutive specimens 51 days. There was no significant sex difference.

There were 43 persons including 26 males whose urine contained typhoid bacilli and then became negative. The median number of days after the first symptoms of typhoid fever that *B. typhosus* was last present was 50, and first absent on two or more successive occasions was 57 days. The median figures for the males were almost the same as those for the females.

LENGTH OF TIME THAT *B. TYPHOSUS* WAS EXCRETED IN FECES

The graph (Figure IV) depicts the length of time after the first symptoms of typhoid fever that *B. typhosus* was excreted in the feces of 63 persons, including the 12 chronic typhoid carriers.

The graph (Figure V) depicts the length of time after the first

FIGURE IV

symptoms of typhoid fever that *B. typhosus* was excreted in the urine of 53 persons, including 10 chronic urinary carriers.

Typhoid bacilli have been found in fecal specimens from the 12 chronic typhoid carriers in the last specimens examined from 495 to 652 days after the onset of illness. The bacilli have been found in the urine of 10 of the above carriers from 121 to 630 days after the first symptoms of typhoid fever.

FIGURE V

Length of Time That *B. typhosus* Was Excreted in Urine

TABLE VIII

LENGTH OF TIME *B. typhosus* WAS EXCRETED BY 12 CHRONIC TYPHOID CARRIERS
REMAINING FROM OLEAN EPIDEMIC

Specimen	Number of Persons	Days After Onset of Typhoid					
		Mean		Median		Range	
		<i>B. typhosus</i>		<i>B. typhosus</i>		<i>B. typhosus</i>	
		First Found	Latest Found	First Found	Latest Found	First Found	Latest Found

Urine.....	10	73	386	70	373	12-169	121-630

The 12 chronic typhoid carriers included 9 married women and 3 married men or three times as many females as males. All the women except one had borne children and that one had symptoms of acute cholecystitis during her illness with typhoid fever. The mean age of the 12 was 44 years, and the range of ages was 27 to 61 years.

Ninety-seven per cent of 391 fecal specimens from the 12 chronic typhoid carriers for a period of at least 16 months after the onset of illness have contained typhoid bacilli.

Urine specimens from 1 male and 1 female typhoid carrier have never contained *B. typhosus*. Thirty-two per cent of 253 urine specimens from the remaining 10 typhoid carriers have shown typhoid bacilli. Some of the urine specimens may have been contaminated by feces. *B. typhosus* was excreted in the urine of the carriers much more intermittently than in the feces.

One of the chronic typhoid carriers who had onset of mild typhoid fever September 28, 1928—diagnosed 2 months later—was probably responsible for 3 cases of typhoid, including 1 death, prior to her dis-

TABLE IX

AGE AND SEX OF 12 OLEAN CHRONIC TYPHOID CARRIERS

Age by Year Groups	Total	Male	Female
All Ages.....	12	3	9
25-34.....	3	0	3

covery and for 2 cases subsequently. (She is one of the 2 carriers who excreted typhoid bacilli in the feces but not in the urine.) Another of the chronic carriers is believed to have given rise to 3 cases of typhoid, including 1 death.

TYPHOID VACCINATION

At city health department and school clinics during the course of the typhoid epidemic 3,990 persons received three inoculations with New York State Department of Health typhoid vaccine, or in a small proportion of cases the mixture of typhoid and paratyphoid A and B vaccine. Physicians in their private practice immunized 671 school children and many other persons.

TABLE X
TYPHOID IMMUNIZATION OF OLEAN SCHOOL CHILDREN

Age in Years	Pupils Number	Pupils Immunized		Days of School Attendance Lost				
		Number	Per cent	Inoc. No. 1	Inoc. No. 2	Inoc. No. 3	Total	
							Number	Per 100 Pupils Immunized
4.....	131	32	24	2.0	1.0	2.0	5.0	15.6
5-9.....	2,213	1,184	54	123.0	108.5	89.0	320.5	27.0
10-14.....	2,219	1,419	64	117.0	183.0	116.0	416.0	29.3
15 & over...	781	516	66	51.0	73.5	65.0	189.5	36.7
Total.....	5,344	3,151	59	293.0	366.0	272.0	931.0	29.5
Total per 100 Pupils Immunized.....				9.3	11.6	8.6	29.5	

Table XI shows the effects of the typhoid immunization of 3,151, or 59 per cent of the Olean school children. The days of attendance lost, per 100 pupils immunized, was 9.3 for the first inoculation, 11.6 for the second, and 8.6 for the third, or a total of 29.5 days. For the three inoculations together the days of school attendance missed per 100 students treated increased from 15.6 at age 4 years to 36.7 at age 15 years and over.

The days of illness due to all three inoculations per 100 pupils immunized was 32.5 of which 13.4 days were due to sore arms, 9.9 to headaches, 8.1 to general reactions, 0.8 to dizziness and 0.3 days to miscellaneous causes. The totals increased from 18.7 days per 100 pupils protected at age 4, to 44.1 days at age 15 years and over. Skin eruptions were noted for 3.1 per cent of the students.

Among the 248 typhoid patients there were 24 who had received

from one to three inoculations with typhoid vaccine during the progress of the epidemic, and 9 who had obtained three injections from 3 to 11 years previously. The latter number included 2 registered nurses and 5 ex-military men of whom 3 were World War soldiers. The number of cases of typhoid fever among the estimated 1,000 World War veterans in Olean was about one-quarter that per 1,000 males of their age group who were not in that war.

COST OF OLEAN TYPHOID EPIDEMIC

The State Legislature has authorized the City of Olean to issue 25-year bonds to the amount of \$425,000 to pay the cost of the care of the Olean typhoid cases and to settle claims. A committee of seven appointed by the Olean City Council had by September 10, 1930, spent approximately \$370,000 and had about 24 unsettled claims, including those for 1 death and for 5 chronic typhoid carriers, of whom 1 typhoid carrier demands \$75,000. The claims committee has in general allowed all bills for physicians, nurses, hospital expenses, and loss of time of wage earners, and made settlements for deaths in proportion to the number of dependents and the earning capacity of the individual before he had typhoid fever.

If the remaining \$55,000 of the authorized bond issues will satisfy the outstanding claims, the average cost per person who had typhoid fever and lived will be about \$1,550. The range has been from nothing to \$16,556 for a railroad conductor age 49 years who became incapacitated as the result of the complications of typhoid fever. The

average for expenses and settlement per death is about \$3,200, ranging from \$714 for nursing and hospital expenses in the case of a 72-year-old physician to \$11,550 for the death of a 56-year-old railroad crew dispatcher who left a family. The \$425,000 would thus be divided into \$345,000 for the living and \$80,000 for the expenses and claims of heirs of the dead.

The payments have by no means completely compensated the typhoid patients and their families for economic losses sustained. It would be difficult to recompense fully the 12 persons who became chronic typhoid carriers. The state, county, and city health departments, the Red Cross, and other organizations had their expenses increased by the Olean epidemic.

The secretary of the Olean Chamber of Commerce estimates conservatively that the direct loss to Olean business because of the typhoid epidemic was \$200,000. The wholesale bakeries which supplied the surrounding area and the other establishments including hotels, which catered to out-of-town trade, were particularly hard hit by loss in patronage.

The enlargement and improvement of the Olean water filtration and chlorination plant since the typhoid epidemic have cost approximately \$125,000, making the total value of the plant now about \$250,000. Plans are being prepared for an improved sewerage system and a sewage disposal plant.

ACKNOWLEDGMENT

I am indebted to Dr. E. S. Godfrey, Jr., Director of the Division of Communicable Diseases of the New York State Department of Health, for kindly furnishing data and helpful criticism; to Dr. E. K. Kline, Bacteriologist in charge of the Diagnostic Laboratory of Cattaraugus County, for supplying the laboratory records, and to Dr. C. A. Greenleaf, Director of the Cattaraugus County School Hygiene District, for making available his tabulations of the typhoid immunization of the Olean school children.

Camp Hygiene and Sanitation

JOSEPH FELSEN, M. D.

New York, N. Y.

THE present paper is supplementary to the studies embodied in a plan for the hygienic and sanitary classification of summer camps published in 1929.¹ In order to secure accurate data contacts were made with all but 3 State Departments of Health, the U. S. Army, the U. S. Public Health Service, executive departments of the large camp organizations (Boy Scouts, Girl Scouts, Y. M. C. A., Y. W. C. A., Camp Fire Girls, Catholic Summer Camps), the National Safety Council, and certain private camp groups. These lay organizations have devoted much time and effort to the study of various phases of camp life. The tourist camp will be briefly considered as a closely related problem.

The possibilities involved in the maintenance of proper sanitary facilities in camps may be surmised from the following figures. According to the 1929 *Handbook of Summer Camps*² there were 2,737 camps distributed through 35 states. Of these, the most densely populated were: New York (394), Maine (230), Pennsylvania (205), New Hampshire (185), Massachusetts (180), California (150), Michigan (116), Illinois (105), Ohio (103), and Connecticut (97). The greatest concentrations are seen about the lake shores of Maine and central New Hampshire, and the hills and valleys of the White, Green and Adirondack mountains. Of 2,776 camps, including 39 in Canada, approximately half (1,346) are private while the remainder are distributed as follows:

Organization	No. of Camps	Population
Boy Scouts	498	300,000
Girl Scouts ³	323	41,472
Y. M. C. A. ⁴	415	101,165
Camp Fire Girls ⁵	101	57,182
Other organizations	90	Not known

These figures do not include the 200 camps operated by the Y. W. C. A.⁶ at which the 1929 attendance totaled 103,000. It will therefore be seen that the 5 major camp organizations alone controlled a 1929 summer population of 602,819 persons.

The tourist camp problem is intimately bound up with improved road conditions and opening of the national park areas. The latter

approximate 11,304 square miles according to the latest available figures. In 1922 approximately 13 million automobiles were owned by the people of the United States and 2,819,386 miles of highways were certified by the U. S. Bureau of Public Roads as being available for use. Solomon¹ estimates the present number of motor tourist camps at 15,000 with a transient population of 3,150,000, including 1 million juniors.

The most complete studies of tourist camps have been made in Minnesota, Florida and West Virginia. In Minnesota there are 175 camps, 160 of which are owned, loaned or rented by the city or village. During 1926 the West Virginia Department of Health made complete inspections of 110 water supplies and certified only 11 as safe. "Safe Water" markers are now posted along state and federal highways in West Virginia, Ohio, Pennsylvania, Michigan, Missouri and Florida. There are no general statistics available relative to disease incidence in summer camps.² The problem as it concerns the public health worker may be divided into food and insect-borne infections, contagious disease and preventable accidents. Only the first will be considered because of its relative importance. The diseases are chiefly typhoid, paratyphoid and dysentery, with typhoid predominating. I have also encountered outbreaks of gastroenteritis apparently due to some member of the salmonella group and associated with faulty sanitation. The clinical manifestations are much like those of bacillary dysentery. The difficulties encountered in tracing some of these outbreaks may perhaps be exemplified by one instance in which infective material seeped through a small break in an old sewer line into the water supply. Large quantities of methylene blue and chromogenic bacterial suspensions failed to come through. It was finally found necessary to excavate the entire system in order definitely to ascertain the source of contamination.

As the typhoid problem, from a public health standpoint, applies to other intestinal infections it alone will be considered. Typhoid fever outbreaks in summer camps are generally secondary to:

1. *Sanitary Facilities*—Poor sanitary facilities whereby typhoid excreta from in or outside the camp reach a water supply not filtered or chlorinated. This is essentially the problem of the sanitary engineer. The drinking water supply and sewage disposal system are the most important factors in the consideration of any camp site. Without their careful planning and supervision infections of intestinal origin will sooner or later manifest themselves. Casual or periodic water examinations for *B. coli* may do much harm by lending a false sense of security to otherwise solicitous camp directors. The possibility of se-

curing suitable connections with the nearest town having a carefully supervised water supply and sewage disposal system should be considered in the choice of a camp site. In lieu of this, the use of properly constructed septic tanks with after-treatment of the effluent (chlorination or sub-surface irrigation) and of filtered or chlorinated drinking water is always advisable. The use of water from open lakes without further treatment is never devoid of danger. Hikers should carry their drinking water from camp or else boil or chlorinate it en route. Disposal of excreta by burial away from a water supply is largely a matter of education by the camp sanitarian and effectual supervision by the councillor in charge.

2. *Carriers*—The carrier problem is becoming more apparent as the various state departments of health enforce the requirement of negative fecal cultures before the final discharge of a typhoid patient. The number of known carriers will undoubtedly increase. Late in 1929 the New York State Public Health Council amended Chapter 2 of the Sanitary Code providing for such cultural examinations, a procedure which had been in force in New York City for some time. It is quite generally conceded that approximately 5 per cent of all typhoid patients remain carriers for varying periods. The State Health Department records show that many were responsible for cases within 12 months after recovery from the disease. Recently the Health Commissioner of New York City claimed that 40 per cent of the serious outbreaks could be traced to carriers. At the end of 1930 this city carried a list of 301 carriers. At the end of 1927 there were 188 known carriers in New York State exclusive of the city.⁹

As a result of improved epidemiological work 41 additional carriers were discovered in up-state New York during 1929, exceeding by nearly 50 per cent the figures of any previous year.¹⁰ By the end of 1930 the total number had increased to 268, making a total of 569¹¹ for the entire state.

A recent example of the carrier problem is the outbreak which occurred during the summer of 1929 in a Pennsylvania camp, involving 61 people with a mortality of 6 per cent. I had an opportunity of culturing the feces of one of these patients in April, 1930, 7 months after recovery, and found typhoid bacilli, a result previously obtained by the New York City Department of Health. That typhoid has diminished somewhat, but still constitutes a formidable problem, may be seen from the following figures. Typhoid fever cases reported to the U. S. Public Health Service, July to September, inclusive,¹² were: 1928, 12,161; 1929, 10,110; 1930, 11,614.

In an attempt to clarify existing legislative enactments regarding the conduct and supervision of summer camps, inquiries were sent to

the health department of every state. Of 45 from which the required data were received 8 (Georgia, Alabama, Vermont, Iowa, Louisiana, North Dakota, Wyoming, New Mexico) had no regulations specifically governing summer camps. The more complete and stringent regulations were found to exist in the Eastern and New England states where summer camps abound. In most states the general sanitary code would, in a sense, apply to summer camps which might come under the supervision of a local health officer. In actual practice, however, it has been found most feasible to enact specific public health measures. The more detailed provisions for camp surveillance exist in Colorado, Florida (tourist camps), Kentucky, Maine, Massachusetts, Minnesota (tourist camps), Missouri, New Hampshire, New Jersey, New York, North Carolina, North Dakota (tourist camps), Ohio, Oklahoma, Oregon (tourist camps), Rhode Island and Virginia. Vermont has no printed rules and relies entirely upon personal visitation by the sanitary engineer.

Special licensing is necessary in New Hampshire, Illinois, Idaho, Maryland, Nebraska, New York, Ohio and North Dakota. An inspection and rating system is in force in Kansas, Illinois, Maine, New York, North Carolina, Oregon and Michigan. Official State Health Department approval by signs or published lists may be obtained in Colorado, Florida, Kentucky, Michigan, Missouri, Ohio, Oklahoma, Texas and West Virginia.

In general, it may be stated that existing regulations may be divided into those which are:

1. Loosely enforced (advisory)
2. Strictly enforced (compulsory)
 - a. Voluntary regulation by lay organizations
 - b. Enforcement by the State Department of Health

In the first group the provisions of the general sanitary code are rather loosely applied to camps because of their short period of existence each year and the desire to avoid loading them with any great financial burden. The compulsory or strict enforcement group regards camps as communities requiring the same strict sanitary supervision as permanent towns or cities in spite of their short lived existence. Compulsory regulations, however, do not necessarily emanate from state departments of health. Many of the large camp organizations and certain private owners have voluntarily set up regulations which not infrequently, in certain states, exceed the requirements of the local or state health departments. Moreover, these bodies are not so unwieldy and slow to convince as local legislatures. Sanitary problems

are more apt to be quickly recognized and solved. An example may be found in Massachusetts where "surveys of camps and records of contagious disease outbreaks have shown that many camps fall short of reasonable health standards."

In order to secure such standards The State Department of Public Health recently asked for a camp licensing law, which, after being proposed, failed to pass. The large camp organizations, on the other hand, seem to have taken the initiative, having accumulated a voluminous literature and issued such publications as *Camping* (Playground Recreation Association of America). The National Safety Council has also collected an extensive bibliography on "Camp Safety Hygiene and Sanitation" and has issued accident and illness follow-up cards in an endeavor to secure data of value in preventive work. The Y. M. C. A. and others are making similar studies.

REASONS FOR THE PRESENT INADEQUATE SUPERVISION OF SUMMER CAMPS

A critical study of existing regulations as promulgated by the various state departments of health suggests the following reasons for the present unsatisfactory state of summer camp supervision:

1. While there is a general recognition of widely accepted public health measures there is some divergence of opinion as to their radical enforcement in the case of summer camps.

2. Efficient and capable state departments of health are frequently hampered by lack of funds. Preventive public health work rarely receives the same monetary support as emergency epidemiological investigations, though the latter are largely the result of the inadequacy of the former. The per capita assessment to cover a state health department budget does not generally take into account the great influx of campers from other states. Young public health recruits are discouraged by the relatively poor compensation for their services.

3. The good work of a health department in one state may be seriously hampered or nullified by the laxity of a similar body in a neighboring state.

4. The lack of accurate data with regard to disease incidence in summer camps.

5. Public health regulations have been outstripped by the rapid growth of the camp movement, shown by the incomplete figures of the Y. M. C. A.:

Year	No. of Camps	Attendance
1900	20	Not known
1926	421	32,213
1929	—	101,165

6. Commercial and political impediments. The desirability of having large camp groups in certain states has not infrequently involved the letting down of customary public health barriers.

SUGGESTIONS FOR ELEVATING CAMP STANDARDS

1. The creation of a central advisory board consisting of a representative each

of the U. S. Public Health Service, U. S. Army, state departments of health, large organized camp groups and private groups. The function of this board would be to collect accurate epidemiological data (e.g., known typhoid carriers), to draw up uniform hygienic and sanitary standards and stress the approval of camps meeting these standards.

2. The more rigid enforcement of existing sanitary regulations by state departments of health.

3. The attitude of state departments of health toward existing camps to be advisory and constructive but without compromise as to accepted sanitary standards.

4. Adequate budget for state departments of health in order to enable these bodies to augment their forces for summer camp work. Personnel may consist of undergraduate public health workers under the supervision of competent, experienced directors. Employment of qualified public health nurses and other professionally trained persons whose occupations permit their accepting summer positions.

5. A resident graduate medical attendant trained in the principles of public health work in or near each camp.

6. Educational campaign among children and adults for 1 month preceding the summer vacation period. Wide dissemination of knowledge concerning summer typhoid and other communicable diseases as well as preventable accidents, through teachers, schools, camp organizations, health department bulletins and lay periodicals.

7. Placarding of all safe drinking and bathing waters, roadside eating places in summer camps and along the main highways.

8. Local purchases of camp food from approved sources.

9. Enforcement of two negative fecal cultures, one urine culture and a Widal for every food handler.

10. Stressing of typhoid prevention work as much as vaccination against smallpox. (I have had several opportunities to note the occurrence of typhoid in recently vaccinated boys who, feeling secure, drank water promiscuously on their daily hikes.)

11. Accurate records, in duplicate, containing the names and addresses of all campers and visitors in order to trace contacts.

12. Minimal toilet seat capacity of one toilet seat per 15 people. The lack of suitable toilet facilities is a rather common cause for the indiscriminate soiling of camp grounds, with its inherent dangers. The laxity in this regard may be illustrated by the requirements of certain states:

State	One seat per			
Maine	15	persons	or	fraction
Connecticut	15	"	"	"
Massachusetts	15	"	"	"
Oregon	25	"	"	"
Washington	50	"	"	"
Oklahoma	15	"	"	"

13. The annual certification and licensing of camps, with revocation at any time for cause.

14. Weekly unannounced inspections with prompt closing after suitable warning of camps falling below accepted standards rather than the repeated publication of approved camp lists or more stringent legislation.

15. Centralization of camp approval in state departments of health rather than by local health officers except where experience and laboratory facilities are adequate.

ADDENDUM

Figures received since this article went to press are as follows:

In 1930 the Girl Scout Camps numbered 544 with a population of 48,077 (Johnson, K. L.); Boy Scout Council Camps numbered 614, which, in conjunction with miscellaneous camps, controlled a population of 320,000 (Wessel, W. C.).

In February, 1931, the National Park areas comprised 16,263 square miles, including 3,741 square miles of National Monuments (Demara, A. E.). In 1929 there were 23,121,589 passenger automobiles registered in the United States and 3,024,233 miles of road available for use, including 314,136 miles of state highways (Fairbank, H. S.).

The Inner Reservoir

“THE ability to make the best use of leisure,” said Dr. Kenworthy, who is one of the country’s leading woman psychiatrists, “is a good test of a person’s adjustment to life. Many individuals find satisfaction in their work, but in their moments of leisure they become restless and uneasy because they have no interests to turn to that will provide the same fundamental release which they derive from their work.

“They are unable to live with themselves, as it were, too fearful to be alone with their own thoughts and, oppressed by a sense of emptiness, they turn to others for relief. They are unable to use their free time as an opportunity for creative self-expression, but only to satisfy a demand for security that is not available within themselves. Their pleasures are therefore mere ways of escape to which they are forced by the lack of adequate personal integration and of the necessary inner adaptation.”—Marion E. Kenworthy, Speech, January 14, 1931, before American Woman’s Association, *Mental Hygiene Bull.*, Jan.–Feb., 1931.

AUGUSTA E. JAY, *Assistant Editor*

TO THE MEMBERS OF THE AMERICAN PUBLIC HEALTH ASSOCIATION:

IT is my pleasure to report to you what I consider the most important event that has transpired in the American Public Health Association in recent years.

I refer to the appointment by the Executive Board of Dr. Kendall Emerson as Acting Executive Secretary. Those of us who have been close to the affairs of the Association count ourselves fortunate that we have been able to obtain the service of a man who has behind him such a brilliant administrative record to manage the business of the Association.

A full account of Dr. Emerson's achievements is recorded in the accompanying editorial. To many of the members of the American Public Health Association he needs no introduction. They already count him a friend. Those who do not know him will hold him in as high esteem, as they encounter his personality, his ideas and his ideals.

Dr. Emerson brings a wealth of seasoned judgment and experience to the problems of the Association. I believe, as does every member of the Executive Board, that he is eminently fitted to carry its best traditions to a new and high goal.

President

DR. KENDALL EMERSON APPOINTED ACTING EXECUTIVE SECRETARY OF THE A. P. H. A.

THE National Health Council, an affiliation of national health agencies, at the request of the Executive Board of the American Public Health Association, has arranged with the National Tuberculosis Association to make available a part of the time of its Managing Director, Kendall Emerson, M.D., to serve as Acting Executive Secretary of the American Public Health Association.

It is believed by the groups concerned that this is a valuable experiment in economy of administrative operation of two national health organizations.

While the plan is of a temporary nature, marked sympathy and interest have been expressed by public health leaders in these organizations, whose aims and objectives are so closely related. The plan contemplates the continuance of full independence and autonomy of each association.

Dr. Emerson was graduated from Harvard University Medical School in 1901, and served his internship at the Massachusetts General Hospital. He later engaged in general practice in Worcester, Mass., and in 1903 became a member of the staff of the Memorial Hospital there, as chief of the Surgical Service. He is a member of the American College of Surgeons.

In 1916 Dr. Emerson went to France as a major in the Royal Army Medical Corps. He served later in the American Army, and after the Armistice became attached to the American Red Cross, serving in Siberia and later in Washington. From 1919 to 1921 in Paris he was Deputy Commissioner and Director of the Medical Service for Europe during the commissionership of Robert E. Olds.

In 1926 he was elected president of the Massachusetts Tuberculosis League and a director of the National Tuberculosis Association. He was elected Managing Director of the National Tuberculosis Association, in New York, in 1928.

Dr. Emerson's services with the American Public Health Association begin April 1.

KENDALL EMERSON, M.D.

STUDENT HEALTH

AT the last meeting of the American Student Health Association held in New York, December 29 and 30, 1930, a set of resolutions covering the whole field of college hygiene and student health was adopted. These resolutions grew out of the desire of the President, Dr. Warren Forsythe, to crystallize out of the association's experience that which could be considered of proven value in college hygiene teaching and student health service practice.

The document proposes in the first place that it is a fundamental objective of higher education to develop the ability of the individual to live a more useful, effective and happy life, and since health (emotional and physical) is one of the greatest factors in the realization of this objective it is a major responsibility of every college and university to carry on a program which will develop and protect the health of the student and educate him in scientific health conservation.

The program is divided into:

1. Instruction in and development of physical and mental health
2. The supervision of the care of individual student health and illness
3. The sanitation of student environment
4. The study of health problems

In the first division of the program it is resolved that instruction should aim to analyze and present scientific information relative to the production, maintenance and improvement of health, with the applications of that information for the health benefit of the individual, his family, and of his society. Further this instruction should aim at developing in the student a discriminating scientific attitude for: (1) the selection and wise use of competent, trustworthy health advisers and skillful, dependable health service; (2) the sifting of health literature, avoiding the hazardous and identifying the scientific and appropriate; (3) differentiating between reliable scientific public health organizations and those that are unsafe; (4) the understanding and regulation of his own health habits. It is further recommended that the teaching of hygiene be under the direction of qualified members of the faculty adequately trained in medicine and public health, and that students receive academic credit for these courses on the same basis as in other curricular subjects.

The native health material occurring in chemistry, psychology, biology and other similar courses should be utilized and emphasized in its appropriate setting. Supervision of the care of student health and illness should be in the hands of a physician who is a full graduate in

medicine and properly licensed to practise in his community. He should also be included in the general faculty administrative agency of the college or university.

There should be complete examinations of all entering students followed by personal health conferences of an educational character and a special endeavor should be made to have all remedial defects corrected. The annual health examination of all students is advised, in which emphasis is placed upon confidential discussion of personal health and emotional problems. Evidence of immunity to smallpox should be one of the requirements for admission and no student should be permitted to remain in school who proves to be a health menace to other students or who refuses to coöperate in the health program of the institution.

It is further resolved that the college should conduct a student clinic for the diagnosis and treatment of all ambulatory cases and provide for hospitalization of all cases which need that service. This service should be supported by health fees payable at annual enrollment and individual visits should not involve the payment of a fee. Each visit to the student clinic should be considered as a lesson in proper methods of procedure in scientific medical practice, and as an opportunity for personal instruction in preventive medicine including mental hygiene. When possible a physician with mental hygiene training or a psychiatrist should be attached to the Health Service staff.

Isolation facilities should be available for all contagious diseases and early isolation of merely suspicious cases should be freely practised. Communicable diseases should be controlled through careful observation of all known contacts, and artificial immunization used when possible. Much of the future progress in preventive medicine lies in the results of the study of so-called pre-clinical illness and the health service should keep clearly in mind its unique opportunity and its responsibility for research in this field. The health service should supervise the sanitary inspection of the premises, buildings, swimming pools, water and milk, and food supplies. All food handlers should be required to submit to annual physical examination. Dietary policies of institution should receive the attention of the health service.

In view of the fact that at the present time several agencies such as department of hygiene, department of physical education, student health service, athletics, etc., each asserts itself as being importantly interested in the health of the college student, it is resolved that there be conducted a careful study of what should be termed specific health activities.

The last resolution calls upon college presidents in rural communities to promote and coöperate with the county health unit under the direction of a full-time medical officer as the most effective method of advancing public health practice in their communities.

The committee consisted of the following: Dr. Anna M. Gove, North Carolina College for Women; Dr. Joseph E. Raycroft, Princeton University; Dr. Dean F. Smiley, Cornell University; Dr. T. A. Storey, Stanford University; Dr. John Sundwall, University of Michigan; and Dr. R. W. Bradshaw, Oberlin College, *Chairman*.

ROCKY MOUNTAIN SPOTTED FEVER DISCOVERED IN EASTERN STATES

ROCKY MOUNTAIN spotted fever has been discovered in the East, it was announced February 27 by the U. S. Public Health Service.

A number of cases of this highly fatal disease have been found in Virginia, Maryland, Delaware, North Carolina and Pennsylvania. At first these were thought to be severe cases of endemic typhus fever but after much experimentation by scientists of the National Institute of Health, they were identified as a disease "clinically indistinguishable from Rocky Mountain spotted fever."

An indication of the possibility of Rocky Mountain spotted fever spreading from its locale and invading other parts of the country was expressed last December in the 1930 annual report of the Service in which it was declared that the disease can be spread not only by specific ticks in the Northwest but also by a certain type of tick which infests dogs, cattle, and a number of rodents which are common throughout the entire country.

Rocky Mountain spotted fever is a very virulent disease, the Service explained, since 60 to 80 per cent of those attacked usually die.

Sixtieth Annual Meeting
Montreal, September 14--17
HEADQUARTERS, WINDSOR HOTEL

ASSOCIATION NEWS

DR. SAMUEL H. DURGIN

1839-1931

DR. SAMUEL H. DURGIN, former chairman of the Boston Board of Health and a surgeon with the Massachusetts cavalry in the Civil War, died at his home in Allston, Mass., on March 6.

Born in Parsonfield, Me., July 26, 1839, he attended Dartmouth College and the Harvard Medical School. Graduating from the latter in 1864 he saw service as an assistant surgeon at Richmond and Petersburg and was present on the field when Lee surrendered.

When he returned to Boston in 1865, he entered into the practice of medicine. In February, 1867, he was appointed Resident Physician for the City Institutions situated in the Harbor and was also made Port Physician. In January, 1873, he resigned this position, having been elected a member of the newly formed Board of Health for the City of Boston and soon after was made Chairman, serving as such until he was retired in 1912.

At the time the Board of Health was established, metropolitan Boston had no drainage system and for years Dr. Durgin fought against determined opposition for the establishment of adequate sewage disposal. He finally won this cause and as a result the metropolitan area of Boston was given what was at that time the most up-to-date sewage disposal system in the country.

Soon after the discovery of diphtheria antitoxin by von Behring in 1894, a plant for its manufacture was started by Dr. Durgin at the quarantine station on Gallup's Island with Dr. Harold C. Ernst, Professor of Bacteriology at

Harvard Medical School, as the director. This was continued until the serum was available from other sources.

SAMUEL H. DURGIN, M.D.

Dr. Durgin was one of the first in the country to inaugurate the requirement of two consecutive negative cultures for release of a case of diphtheria, the second culture taken at least 24 hours after the first and by a medical representative of the department. Dr. Durgin was the inventor of the wooden tongue depressor now so widely used throughout the civilized world.

From 1884 to 1909 he was a lecturer on hygiene in the Harvard Medical

School. He was trustee of the Floating Hospital for many years and was actively interested in its work. Dr. Durgin was president of the American Public Health Association in 1893. He became a member of the Association in 1875, was made an honorary member in 1916, and an Honorary Fellow in 1922. He was the oldest member of the Association.

NEW FIELD DIRECTOR OF THE COMMITTEE ON ADMINISTRATIVE PRACTICE

CARL E. BUCK, Dr.P.H., formerly Deputy Commissioner, Executive Officer, and Secretary, of the Detroit Department of Health, has been appointed Field Director of the Committee on Administrative Practice of the American Public Health Association. He succeeds W. F. Walker, Dr.P.H., who resigned, as of April 1, to go with the Commonwealth Fund as Director of the Division of Public Health Studies. Dr. Walker has been with the Association since 1925.

Dr. Buck was a member of the American Sanitary Commission to the Balkan States in 1915 during the typhus fever outbreak in Serbia. He was Health Commissioner of Oak Park, Ill., 1916-1917. He served in the Air Service of the U. S. Army during the World War. After the war he was a member of the staff of the International Health Board of the Rockefeller Foundation, doing malaria work in the southern states. At the time Dr. Kiefer was made State Health Officer of Michigan Dr. Buck was loaned by the Detroit Department to the State Department as administrative assistant. He was president of the Michigan Public Health Association, an affiliation of the A. P. H. A., in 1929.

Dr. Buck's work with the A. P. H. A. begins April 1.

WESTERN BRANCH, AMERICAN PUBLIC HEALTH ASSOCIATION

THE Seattle meeting will be May 28-30. An excellent program is being planned. Medical economics in relation to public health will receive a prominent place on the program. Infantile paralysis, which may be expected in the Pacific Coast and intermountain states this coming summer, will receive considerable attention. California's experience with the extensive use of convalescent serum will be described.

Public health education from the standpoint of the general public, public health nurse, medical social worker, and the medical student, will be one of the leading symposiums.

Public health nursing will be given a prominent place under the leadership of Elnora Thomson and Elizabeth Soule, both of the Pacific Northwest. Sanitary engineering, food control, and sanitary inspection will all have places on the program.

DEATH OF THOMAS F. KENNEY

THOMAS F. KENNEY, M.D., Director of Public Health in Worcester, Mass., since 1919, died March 15 at the Peter Brigham Hospital, Boston. Dr. Kenney was recognized throughout the country as a leader in the field of public health. For several years he has given a special lecture course in health subjects at the Massachusetts Institute of Technology. He was the Health Officers Section representative on the Committee on Training and Personnel of the A. P. H. A. He has been a member since 1918, and a Fellow since 1922.

ON April 6, the American Public Health Association, with other members of the National Health Council, will move its executive offices to 450 Seventh Avenue.

PUBLIC HEALTH ADMINISTRATION

HENRY F. VAUGHAN, D. P. H.

Survey of Use of Preventive Medical Services for Preschool Children

—The study pertains wholly to preschool children, those under 6 years of age, and involves 140,000 children in 146 cities and 37,000 in the rural sections of 42 states. Information was sought with regard to the application of four preventive measures: (1) Health Examination, (2) Dental Health Examination, (3) Vaccination against Smallpox, (4) Immunization against Diphtheria.

The survey information was collected by local health workers who followed a prescribed method of questioning parents, and the results are comparable just in so far as such instructions were followed. The health examination meant a visit to a doctor to see how the child was getting along even though he were not sick. In like fashion the dental examination meant a visit to the dentist not because of a toothache but just to have the teeth looked over with a view to preventing trouble.

Districts to be surveyed in the cities were chosen around the public schools as a center with the view of securing a cross-section of the various economic groups in the population, there being established for this purpose five such groups. The selections were made by the committee so as to give a very fair cross-section of the population. The rural data were obtained from families living in the open country or from communities under 2,500 population.

How many children under 6 years of age have had a health examination? The leading cities are: Berkeley, Calif., with 82 per cent; Providence, R. I., 76;

Lakewood, O., 75; Utica, N. Y., 73; Cleveland Heights, O., 72. For the average United States city 48 per cent of the preschool children have had a health examination.

At what age are the health examinations given? Compilation of statistics from cities indicates that for infants under 1 year of age, 57 per cent have been examined; for the 1-year group, 54; for the 2-year olds, 50; for the 3d year, 48; 4th year, 48; and 5th year, 52. The inference to be drawn from these figures is that there are practically no health examinations after the 1st year. The figure of 52 in the 5th year means that 52 per cent of the children 5 years of age, some time in their lives, have had a health examination. This does not mean just during the 5th year, but at any time up to and including the 5th year.

Although the difference is not great, the highest economic group in the community has been better served, the lowest having received the poorest service, only 43 per cent having been examined in comparison with 62 per cent for the highest economic group.

In the average United States city, 10 per cent of the preschool children have had a dental health examination. The leading cities were: Cleveland Heights, O., 46 per cent; Newton, Mass., 42; Kansas City, Mo., 34; Berkeley, Calif., 33; Salt Lake City, Utah, 29. Among the relatively well-to-do, about 1 child in 5 has had a dental health examination while in the poorest economic group only 1 in 25 has had such examination. In general, it may be said that dental attention is not commonly sought and

there is apparently little of this work being done for the poorer children.

For the average American city, 14 per cent of the preschool children have been vaccinated against smallpox. In New York City there have been vaccinated 48 per cent; Yonkers, N. Y., 47; Providence, R. I., 40; San Francisco, Calif., 36; and New Haven, Conn., 35.

In the average United States city, 15 per cent of the preschool children have been immunized against diphtheria, the greatest progress at the time of the survey having been made in Niagara Falls, N. Y., with 50 per cent; Syracuse, N. Y., 49; New Haven, Conn., 46; Yonkers, N. Y., 46; and Utica, N. Y., 45. The children of the higher economic groups are receiving the most immunization although the situation varies considerably in individual cities. For example, in Des Moines, Ia., 31 per cent of the highest economic group are protected and only 3 per cent of the lowest, while in Boston, Mass., but 14 per cent of the highest economic group and 29 per cent of the lowest are immunized, indicating, it is believed, that the public clinics are very active in Boston while the private practitioners are doing very little. The contrary is apparently true in Des Moines. Detroit seems to present a picture in which all economic groups are receiving about the same attention. For the highest group, 43 per

cent have been immunized; the second, 30 per cent; the third, 42 per cent; the fourth, 37 per cent; while in the fifth or lowest economic group, 42 per cent have been immunized. This is of interest in showing what happens in a city where the health department has given up all free clinics and where all preventive work is done by the general practitioner and the educational program is carried on by the department of health. Among the 36 largest cities, Detroit stands second in percentage of children immunized at the time of the survey, Detroit having 40 per cent and Rochester, N. Y., 43 per cent immunized. In Detroit, all of this work has been done by the coöperating physicians and none by the Health Department, which organization has, of course, carried on the educational and propaganda work.*

In arranging the cities in sequence from the highest percentage to the lowest in each of the four health measures, a composite rating has been obtained which places in the lead Cleveland Heights, O., followed by San Francisco, Calif., Berkeley, Calif., Kansas City, Mo., and East Orange, N. J.—George T. Palmer, presentation before the White House Conference on Child Health and Protection, February 19, 1931.

* Since this survey was made in September, 1930, the percentage of preschool children immunized in Detroit has been increased to 55.

LABORATORY

JOHN F. NORTON, PH.D.

AN IMPROVED WATER SAMPLE BOTTLE

ROSS L. LAYBOURN, F. A. P. H. A.

State Board of Health Laboratories, Jefferson City, Mo.

THE collection of water specimens for bacteriological analysis by untrained persons is never desirable, yet many situations arise in state work in which, from the standpoint of expediency at least, it seems desirable to accept such specimens. One of the common causes of misleading results under such conditions is the contamination of the stopper of the sample bottle during the collection of the specimen. In an attempt to reduce the possibility of the contamination of bottle stoppers to the minimum, the device shown in the accompanying illustrations was perfected in the Laboratories of the State Board

Glass stoppered, metal capped bottles of a type which can be purchased from physicians' supply houses are used. Two holes are drilled in the metal cap in which the ends of a clip of spring

of Health of Missouri several years ago, and has been found to possess sufficient merit to justify the additional expense involved in its use.

brass wire are inserted. This clip retains the glass stopper well within the metal cap where it is not easily subjected to contamination even if the cap is placed on some object during the collection of the specimen. This arrange-

ment has the additional advantage of making it unnecessary to place a strip of paper between the stopper and the neck of the bottle to avoid breakage during sterilization. In preparing these bottles for sterilization, the caps are simply placed loosely on the neck of the bottle and are screwed down tight after removal from the sterilizer.

The glass used in the standard commercial bottle etches quite rapidly under repeated sterilization and soon presents

a very unattractive appearance, and these bottles are also much in demand as replacements in medicine cases. To overcome these disadvantages, a bottle manufacturer is now supplying a bottle of a better grade of glass which withstands repeated sterilization and, as this bottle has the name of the laboratory blown into the glass and does not have the flat side necessary for use in medicine cases, distribution losses are largely eliminated.

VITAL STATISTICS

LOUIS I. DUBLIN, PH. D.

Unsuspected Physical Defects—The Heart Council of Cincinnati has reported the second of a series of studies on the physical status of persons engaged in certain kinds of work. The objective was to determine the extent of diseases of the heart and vascular system. The second report embraces the examination of 1,000 white, male, machine and hand tool operators. The report is mainly a series of tables, from which one is left to draw one's own conclusions.

It was found that 87.1 per cent of the group of 1,000 had been vaccinated in some way; 80.2 per cent of them had been vaccinated against smallpox, 22.5 per cent against typhoid, and 21.9 per cent against diphtheria; only 67 per cent of the workers were considered to be on an adequate diet; 56.3 per cent of them had no illness within the last 10 years.

The cardiovascular lesions noted were indeed numerous. The 45.8 per cent in whom such lesions were found did not include observations of such unproved significance as extrasystoles, trivial hypertrophies and arrhythmias. Those, however, whose lesions were considered

significant constituted 31 per cent of the group. The importance of early infections on the heart in later years is shown by the fact that 21.9 per cent of those who had significant heart lesions have a history of illness in the past from some of the common infectious diseases.

A relation between excessive weight and myocardial hypertrophy is indicated by the fact that 49.3 per cent of those who were 20 pounds or more above normal weight had myocardial hypertrophy, while only 5.3 per cent of those who were 20 pounds or more underweight had any cardiac lesion. Of the whole group of 1,000 machine and hand tool operators, 83.6 per cent had significant defects of some kind and 88.5 per cent had defects unknown to them or of which they had not complained.—*J. A. M. A.*, 96: 119–120 (Jan. 10), 1931.

What is a Stillbirth?—An investigation into the many different definitions of stillbirth and into the laws and religious customs attended with the recording of births as live or stillbirths in the different countries and states of the United States indicates that the discrepancies are so great as to render

comparative statistics on stillbirth and infant mortality practically valueless.

In the Province of Quebec (as in some other localities throughout the world) where there is a preponderance of the Roman Catholic faith, there is a tendency, whenever there is a doubt that a new-born child is born alive or not, to report it as a live birth to give the child the benefit of baptism. As a consequence the stillbirth rate in Quebec is lower and the infant mortality rate higher proportionately than in Protestant communities.

In Canada, the age at which a fetus is considered as a live or stillbirth varies: in Manitoba at 5 months; Alberta at 24 weeks; Quebec and Saskatchewan at 6 months; British Columbia at 28 weeks; Prince Edward Island, New Brunswick and Ontario at 7 months. In all the nine provinces there is variance as to what is considered an evidence of life in a new-born fetus or child.

The annual collection of stillbirth statistics in the United States was begun in 1922. The interpretation of these statistics must necessarily be governed by the differing regulations of the states for the period of uterogestation to which a stillborn child must have advanced before a certificate is required to be registered. In 18 states, registration is required after 4 full months, in 2 after 4½, in 3 after 5, in 3 after 6, in 2 after 28 weeks, in 3 after 7 months; in New Hampshire and Delaware there is no definite rule; and in Maryland any product of human gestation that may be recognized as such must be registered.

In Austria the law prescribes that all children who, being born dead, have reached a state of development which indicated the possibility of independent existence, are to be registered; but that all others, which means non-viable children, are to be regarded as abortions or miscarriages and registration of such

births is not required. It is remarked that in Roman Catholic districts, still-born children are baptized, and as registration of birth is made by the religious communities, registration of some stillbirths is made as live births, rendering the stillbirths statistics inaccurate.

In Spain, registration of all stillbirths is compulsory since 1919. Registration which includes those born without signs of life, and those born alive but dying within 24 hours after the severance of the umbilical cord, must be effected within 24 hours of the occurrence of such birth.

In the Republic of Portugal a special register is kept for stillbirth but no definition of live or stillbirth is given. In Belgium, officially a stillbirth is defined as the birth of a dead child after the 180th day of gestation. In Holland, the procedure is quite similar to that followed in Belgium with the exception that no mention is made of the period of uterine gestation. In Denmark, a footnote on the birth certificate gives the following definition of a stillbirth:

Premature born children, born alive, to be recorded as live births. And a fetus born without obvious signs of life in the 29th week of pregnancy or after should be recorded as a stillbirth; but if born before the 29th week it should be deemed a miscarriage and not recorded.

In Norway, stillbirths are defined as births without life after the 28th week of pregnancy. Abortion and stillborn fetuses born before the end of the 28th week are not to be registered. In England and Wales, no record of stillborn children may be made in a register of births and deaths. But, if a child is born alive, it matters not how soon it may die, both the birth and the death must be registered. A child is deemed to be stillborn when, after being completely born, it has not breathed or shown any sign of life. The term completely born is understood to indicate

complete expulsion from the body of the mother, independently of complete separation. No mention is made of the product of miscarriage or abortion, and it seems that whenever a child is born alive according to the above definition whatever be its fetal age, a live birth is registered.—Eugene Gagnon, *Canad. Pub. Health J.*, 22: 16–27 (Jan.), 1931.

Statistics for Northern Ireland—The latest enumerated population of Northern Ireland, obtained for the Census of 1926, is 1,256,561. The estimated population in the middle of 1929 is 1,246,000, including military. The results of the year's registration show that a further increase in the marriage rate has been accompanied by a further decrease in the birth rate, and that for the first time since 1924 the death rate has increased.

Births registered during the year numbered 25,410, a decrease of 553, or 2.1 per cent, as compared with the previous year. The birth rate was 20.4 per 1,000 of the estimated population, being 0.4 below the rate for the previous year and 2.4 lower than the average rate for the 10 years 1919–1928. The proportion of male births to every 100 female births was 105.5. Deaths registered during the year numbered 19,822, an increase of 1,818 or 10.1 per cent, as compared with the previous year. The death rate was 15.9 per 1,000 of the estimated population, being 1.5 above the rate for 1928 and 0.2 above the rate for the previous ten years 1919–1928. The relatively high death rate of 15.9 per 1,000 in 1929 is due mainly to a large increase in the number of deaths from influenza, bronchitis and pneumonia, as a result of an epidemic in the first quarter of the year.

The influenza epidemic had the effect of increasing the death rate from this disease to 107.1 per 100,000 of the population, compared with an average

rate of 59.4 for the years 1919–1928. Deaths from all forms of tuberculosis show a decrease of 7.7 per cent on the number registered in the year 1928, the death rate being 129.3 per 100,000 in 1929, and 139.6 in 1928, while the average for the last 10 years preceding 1929 was 169.0. Cancer has shown an increase every year since 1922, with the exception of 1926 and 1928, when slight decreases were recorded. In 1929 the mortality rate was 117.9 per 100,000. Puerperal mortality in 1929 was 6.26 per 1,000 births as compared with the previous 10 years' average rate of 6.18.

Deaths of infants under 1 year of age numbered 2,174, or 86 per 1,000 births registered, as compared with 78 per 1,000 in 1928, and an average of 84 per 1,000 for the 10 years preceding. In 1929 and 1928 the rates for deaths of infants under 1 year of age were 74 and 65 per 1,000 births, respectively, for England and Wales, 87 and 86 for Scotland, and 70 and 68 for the Irish Free State.—*The Registrar-General's Eighth Annual Report*, Government of Northern Ireland, pp. 6–24, 1929.

The Extent of Gonorrhea and Syphilis in the United States—A series of prevalence studies has been carried out in communities with a total population of more than 17,758,000 located in various parts of the United States, and representative of the population as a whole. It is estimated that there are in the whole country 643,000 cases of syphilis and 474,000 cases of gonorrhea constantly under medical care. Twenty-one per cent of the cases of gonorrhea and 40 per cent of the cases of syphilis are treated in public clinics.

The combined case rate for gonorrhea and syphilis for the male population was nearly twice as high as that of the female, the rates being 9.65 and 4.85 per 1,000, respectively. This difference

was more pronounced for gonorrhea than for syphilis.

Venereal diseases as a group far outnumber all other reported infections except influenza in times of an epidemic. The experience in the military forces of this and other countries in peace and in war time shows the venereal diseases to exceed any other condition as a cause of noneffectiveness. Among the second million men drafted during the World War, 56.7 per 1,000 were found by a casual clinical examination to have a venereal disease.

It is estimated that in the continental United States there are 423,000 new cases of syphilis which seek treatment during the early stage (the first year) of the disease, and, likewise, 679,000 new cases of gonorrhea each year which come under medical care during the first three months of the infection. This incidence represents an annual attack rate per 1,000 population of 3.46 for syphilis and 5.71 for gonorrhea. Par-ran and Usilton (*J. Soc. Hyg.*, 16: 31, 1930), estimating 643,000 cases of syphilis and 474,000 cases of gonorrhea constantly under medical care in the United States, give case rates for gonorrhea 4.88 for males and 1.78 for females; for syphilis 4.77 for males and 3.08 for females.

Approximately 31 per cent of the total cases of venereal diseases under treatment are found among presumably indigent persons, inasmuch as this percentage of total cases were being treated at public expense in clinics, hospitals or other institutions. The peak-age group for the onset of both gonorrhea and syphilis has been determined as 20 to 25 years.

A greater prevalence of venereal disease exists among the negroes than among the white population, the rate per 1,000 being 8 for white and 11 for colored population. A recent study of the rural negro in a southern state indicated that as high as 24 per cent of the

entire population of more than 1 year of age showed a positive Wassermann reaction.

The results of a number of published reports over a 10-year period indicated that of women admitted to maternity hospitals 6.9 per cent had a positive Wassermann reaction. General paralysis contributes 4 per cent of the population of our insane institutions. Syphilis stands first or second among the most frequently reported infections to the U. S. Public Health Service from the state health departments. Gonorrhea stands about fifth.

Among the general male population between the ages of 15 and 45 years it is estimated that the number of non-effective days lost through venereal diseases would approximate 21,000,000 days per annum, or a loss of approximately a half a day for each male of the United States between the ages of 15 and 45 years.—*Am. J. M. Sc.*, 158: 873-874 (Dec.), 1930.

Vital Statistics in England and Wales, 1929 and 1930—The economic depression in England and Wales seems to have had little effect upon the marriage rate of the country. During 1929 there were 15.8 marriages per 1,000 population; this was the highest rate since 1921. On the other hand the birth rate of 16.3 in both 1929 and 1930 was the lowest ever recorded since the establishment of the civil registration. The birth rate was the lowest of any European country except Sweden in 1929. In France the birth rate, which before the war was the lowest in Europe, has decreased more slowly than in most countries so that in 1929 it ranked above England and Wales, Norway, Sweden and Switzerland.

The death rate of 13.4 per 1,000 population in 1929 was the highest since 1919. The high rate was caused chiefly by an increase in the deaths from influenza and other respiratory diseases,

whooping cough and diseases of the heart. The first quarter of 1929 was marked by a period of severe weather, the coldest since 1895, and was accompanied by a serious outbreak of influenza. Preliminary reports for 1930 show a considerable decrease in mortality to a rate of 11.5, the lowest on record.

The adverse conditions of 1929 were also responsible for the increase in the infant mortality rate which rose from 65 per 1,000 live births in 1928—the lowest hitherto recorded—to 74 in 1929. According to preliminary reports for 1930, however, infant mortality reached a new low rate of 60 during the past year.—*Manchester Guardian Weekly*, 24: 129 (Feb. 13), 1931; *Lancet*, 1: 203 (Jan. 24), 1931; *Registrar-General's Statistical Review of England and Wales*, 1929.

Vital Statistics of the Irish Free State, 1929—The annual report of the Registrar-General of the Irish Free State for 1929 estimates that the population of the State in the middle of the year was 2,946,000. The figure given by the census of 1926 was 2,972,802. There is an increase in the number of deaths as compared with 1928, and a decrease in the numbers of births, of marriages, and of emigrants. The deaths represented a rate of 14.59 per 1,000 of the estimated population, the total number of deaths being 42,991. Of the causes of death, heart disease is placed highest with 5,616; tuberculosis next with 3,875; followed by cancer with 3,116; and influenza 1,659.

There has been an increase in the number of deaths by violence from 883 to 971; this is mainly due to two distinct causes—the increase of deaths from motor accidents, and an increased number of suicides. The total number of deaths from all forms of vehicular transport increased from 150 to 200, the number of suicides from 98 to 111. Up

till recently suicide was uncommon in Ireland, but it appears to be taking a place among the considerable causes of death.

The mortality from tuberculosis continued to show a gratifying decline. In 1919 the number of deaths from tuberculosis was 5,839, and in 1929 was 3,875, almost every intervening year showing a fall. The deaths from cancer are 74 fewer than in 1928.

The infant mortality was 70 per 1,000 births. The birth rate shows a decline when compared either with the rate in 1928 or with the average in the 10 years 1919–1928. In the period 1911–1915 the birth rate was 24.9 per 1,000 of the population; in 1924–1928 it was 20.57; in 1929 it was 19.78.

Illegitimate births constituted 3.2 per cent of the total. The mortality among illegitimate children was appallingly high; no less than 29.4 per cent died within the first year of life—a mortality more than four times the general infant mortality. The net emigration for the year—18,145—was the lowest on record, the average for the period 1911–1926 being 26,946. Nevertheless, it was more than enough to counterbalance the natural increase of population, or excess of births over deaths.—*Lancet*, 1: 156 (Jan. 17), 1931.

One Hundred Thousand Deaths—Ninety-seven thousand people were killed in the United States by accidents in 1929; this figure is likely to be increased to 100,000 before the year 1930 closes. Accidents this year will account for more deaths in the United States than does tuberculosis. Among males, accidents are second in importance to heart disease as a cause of death, and tuberculosis is seventh.

The 1929 accident fatalities exceeded those of 1928 by 2 per cent; but there was an increase of 28 per cent since 1920. The accident death toll of 97,000 last year is about 2,000 in excess of the

figure for 1928, an increase as large as any which has occurred in any single year since 1925. The 1929 accident fatalities had their origin in the home in 23,000 cases. The hazards of occupation accounted for another 23,000 deaths. In public places, there occurred some 51,000 deaths. The 51,000 fatalities in public places included 31,000 arising out of the use of motor vehicles. These 31,000 automobile deaths were the outcome of not less than one million injuries. These figures show an increase in motor vehicle deaths alone amounting to 3,000, or more than 10 per cent over the 1928 figure. Preliminary figures for 1930 show an increase of 4 per cent for the current year; or a total of some 33,000 deaths in automobile accidents before the end of the year.

Down to 1926, there had occurred each year a decrease in the number of fatalities per 100,000 cars registered. But beginning in 1927, this figure rose to 100.2 deaths for 100,000 automobiles; in 1928, the figure was 101.7, and in 1929, the fatality rate on the basis of 100,000 automobiles registered was 104.5. The highest death rates from automobile use occurred in the Pacific Coast States—34.5 per 100,000 in 1928; the lowest in the West South Central States (14.1 per 100,000). Contrasting urban and rural experience, we find in cities over 100,000 population the increase was from 21.1 to 23.8 per 100,000 or 13 per cent; in rural areas, the rate increased from 12.1 to 16.4 per 100,000 or 27 per cent between 1925 and 1928 or twice as fast as in the large cities. Deaths of children in automobile accidents decreased from 5,110 in 1927 to

4,943 in 1928. In 1928, 19.8 per cent of all automobile fatalities were of children under 15 years of age; in 1922, the figure was 29.4 per cent. According to the Interstate Commerce Commission, railroad grade crossing deaths involving automobiles were 2,102 in 1929, a decrease from 2,170 registered in 1928. Railroad crossing accidents where passenger automobiles were involved caused 1,741 deaths in 1929, a decrease from 1,820 in 1928.

Other public accidents not involving a motor vehicle accounted for some 20,000 deaths last year. Of these, some 8,500 were drownings, with July as the peak month. Persons under 25 years of age accounted for 56 per cent of the drownings. Firearms accounted for 3 per cent of all accidental deaths, or an annual toll of 3,000 in the United States. It was reported that for the 30,000,000 school children in the United States, some 700,000 accidental injuries occur annually, with 6,300 ending fatally. Accidental injury accounts in all probability for about 2,700,000 days of absence in our schools annually. Of the 23,000 fatalities in the home during 1929, in the United States, falls account for 40 per cent; burns, scalds and explosions for 24 per cent; asphyxiations for 14 per cent; and poisons for 9 per cent. The United States heads the list of all civilized countries of the world in its accident death rate—79.2 per 100,000. 'Canada was next in point of accident fatality rate, with a figure of 62.5 per 100,000; England and Wales had an accident death rate of 41 per 100,000, almost one-half the figure for the United States.—*Trans. National Safety Council*, 3: 3-7, 1930.

PUBLIC HEALTH ENGINEERING

ARTHUR P. MILLER, C. E.

CONTROL OF CROSS-CONNECTIONS IN TEXAS CITIES

W. N. DASHIELL AND EDGAR WHEDBEE

Sanitary Engineer and Assistant Water Supply Engineer, Dallas, Tex.

PRIOR to about 1926 cross-connection of private water supply systems with the public water supply systems of practically all of the cities of Texas was permitted without much thought being devoted to the protection of the city supplies. There were no ordinances or water department regulations dealing with this question and in nearly all instances no records were kept of the location or any of the details of the connections. As underground water is comparatively plentiful in Texas, there has gradually developed a cross-connection problem in practically every city in the state.

There are no specific laws governing the installation of cross-connections in the *State Sanitary Code* which is used as a basis for the activities of the Sanitary Engineering Bureau of the Texas State Department of Health. A revision of the code presented during the 41st legislature, which met early in 1929, failed to pass, due possibly to the time required by more popular pending legislation than to any organized opposition.

A section of this proposed code provided that after December 31, 1930, no physical connection between the distribution system of a public water supply system and that of any other system shall be permitted unless such other water supply is of a safe sanitary quality, and the interconnection of both supplies is approved by the State Department of Health, and further provided

that where such physical connection existed and included two gate valves with indicator posts, two check valves of a design approved by the State Department of Health with drip cock and gauges for testing all located in a vault of water-tight construction, readily accessible for inspection, the date of discontinuance may be temporarily extended with the permission of the State Department of Health.

In the absence of effective legislation the work of cross-connection elimination has developed rather slowly. Perhaps the most effective work has been done in cooperation with the U. S. Public Health Service in its program of certification of water supplies used by common carriers operating in interstate traffic. Approximately 180 of the 500 or more largest water supplies in Texas both privately and municipally owned come under the federal certification procedure.

The Texas State Department of Health Division of Sanitary Engineering takes the position that all cross-connections are potentially dangerous and that every city should make a thorough cross-connection survey with a view to securing the prompt elimination of the more undesirable ones and to furnish data as a basis for developing a definite program for the gradual elimination or satisfactory correction of each. During 1928-1929 such surveys were instituted in Dallas, Fort Worth, Houston,

and San Antonio, and in several smaller cities.

The action taken by these cities has been followed by many others in starting programs of cross-connection control largely through educational and corrective procedure rather than enforcement through ordinance.

This paper deals only with that phase of cross-connection control relating to dual supplies for fire protection and auxiliary domestic and industrial supplies. The elimination of other cross-connections, such as with plumbing fixtures and swimming pool filters, has been largely attempted by educational means, through the efforts of the State Health Department and the Association of Master Plumbers.

During the spring and summer of 1929, the City Water Department of Dallas, coöperating with the State Department of Health, conducted a cross-connection survey of its water supply system. This survey was made as a part of the permanent program which Dallas now has under way to correct various sanitary defects in the public water supply system in order to secure unconditional certification on the basis of the Treasury Department Standards.

A list of 184 potential cross-connections which had been compiled by the Dallas City Health Department was found, to which additions had been made at intervals by the Water Department without complete confirmation by field investigation. These were the only available records at the beginning of the survey.

The procedure adopted was to visit all premises listed and where investigation revealed the presence of cross-connections detailed sketches and descriptions of the physical layout, showing points of interconnection, sizes of lines, valve control provided, static pressures and other pertinent information were prepared. In every instance where a secondary supply was found, consider-

able time was spent in definitely establishing the separation of the two supplies.

As a result of the survey, 44 cross-connections were located of which 8 were readily eliminated. Four of the connections were with supplies obtained from shallow dug or driven wells, and 3 with grossly polluted water.

The remainder of the group, 37 deep drilled wells used as auxiliary supplies for office buildings and industrial plants, compares well with the primary supply from the standpoint of potability and safety. With but one or two exceptions they are pumped by air lift apparatus. Three water bearing sands are used extensively in this area as follows: the Woodbine sands from 950-1,000 ft., the Paluxy sands from 1,600-1,800 ft. and the Trinity or basement sands from 2,200-2,400 ft. These lie in the Comanchean or Lower Cretaceous formation of the Mesozoic era and until very recent years produced artesian wells.

A number of the wells were subject to overflow from storm water or stoppage from sewage collection lines. Many of the ground reservoirs into which the wells discharge were open and subject to surrounding contamination.

There were no double check valve installations, and single cast iron checks were commonly used in the fire protection connections. Still other connections were found without check valves and in these the manipulation of one or two gate valves would establish an open connection with the primary supply. In nearly every instance there was no periodic bacteriological control of the water.

Effective July 1, 1929, the Dallas Water Department, through its Industrial Engineering Division, instituted a standby service charge affecting those industries which had city water connections and maintained a private secondary water supply. The charge is based on the average total monthly consump-

tion of each institution from its several water supplies, taken from the records of the preceding year. As Dallas does not have a sewer rental, the benefits of city water and sewer service were donated to those industries maintaining a secondary water supply system, prior to the time the standby charge was instituted. In March, 1930, Dallas passed an ordinance prohibiting any new cross-connections; providing for the disconnection of unsafe interconnected water supplies; and outlining sanitary improvements for the remainder of the cross-connections, including supervision by the Dallas Water Department; and further providing that after June 1, 1935, cross-connections heretofore provisionally permitted should be removed.

As a result of the above outlined activities of the Water Department, together with the establishment of a new attractive schedule of water rates for industrial consumers, there are at present only 5 cross-connections with the public water supply system, and it is expected that all will be eliminated within the next year or two. The Water Department also reports that its industrial water sales have been increased by the amount of 5 million gallons per day. At an average rate of \$.12 per 1,000 gallons, this increase represents additional revenue of approximately \$15,000 per month.

Heavy rainfall upon the watershed of Buffalo Bayou in the last days of May, 1929, resulted in the flooding of the central water supply pumping plant of the City of Houston and showed the necessity for emergency relief measures being instituted. A reorganization of the City Water Department was effected to include a sanitary engineering division, the duty of which should be to administer a definite improvement program for the water supply system. Houston obtains its water supply from deep drilled wells located at 8 pumping stations in the city.

Part of the program of the Sanitary Engineering Division was to conduct a thorough cross-connection survey of the water supply system. With these data as a basis a cross-connection control ordinance was prepared and adopted during March, 1930. Reports made to the State Health Department show that up to the time the ordinance was adopted approximately 57 cross-connections had been surveyed by the division. We have been unable to secure accurate information of the progress of elimination since the adoption of the ordinance last March.

San Antonio made a survey of cross-connections with the public water supply system in the early months of 1930. The survey was made by the San Antonio Water Board in an attempt to remove defects in the public water supply system listed as such in the water certification procedure. Thirty-two cross-connections were located as a result of the survey and a water board order was passed reaffirming the policy of not permitting any new cross-connections, and providing for the elimination of all existing connections. At present there are reported to be only 3 cross-connections and plans are under way for their elimination.

It is reported that the last cross-connections at Galveston were eliminated about two years ago and that no future cross-connections will be allowed in accordance with the city health code.

Fort Worth has had under way during the last year a program of cross-connection elimination similar to the one being carried out in Dallas. The water bearing strata from which Fort Worth derives its private well supplies are the same as those from which Dallas obtains the major part of its private supplies. The dip of these strata is such that their depth is approximately 1,000 feet less in Fort Worth than in Dallas. The procedure adopted in making the survey is similar to that em-

ployed in Dallas and the work is being conducted jointly by the City Health and Water Departments.

Approximately 15 cross-connections have been eliminated as a result of the survey and there still exist for correction about 30 connections with private water supplies.

Fort Worth also has a publicly owned separate raw water system, supplied with Trinity River water, maintained primarily for fire protection and street cleaning. Nineteen cross-connections between this public raw water system and the public water supply system have been surveyed. All of these were made for the purpose of securing a dual supply for building fire sprinkler systems. The pressure in the raw water mains is approximately 20 lb. per sq. in. higher than that normally maintained in the domestic system. Sixteen of the 19 connections have double cast iron check valves for the protection of the city supply and the remaining three have a single cast iron check valve. Many of these valve installations are so located as to be inaccessible to periodic inspection and several of the vaults are flooded with water. One installation had the check valves buried in concrete. The public raw water system was built in 1911 and there are no records to show that the check valves have been inspected since their installation.

An ordinance requiring physical separation of the raw water system and all private water supplies from the domestic system has been drafted and will undoubtedly come before the City Council

for passage within the next few weeks. The present policy of the water department is not to permit new cross-connections and to work toward the elimination of the existing ones pending the passage of a control ordinance.

In addition to the brief résumé of the above activities, considerable work has been done in many smaller Texas cities. At Texarkana 6 cross-connections between the privately owned city water system and private water supplies were eliminated this year in approximately 6 weeks following a survey by representatives of the Texas State Department of Health and the Texarkana City Health Department. Similar work has been done at Beaumont, Port Arthur, Orange and other places.

While the program as a whole has been extended over a considerable period of time, but more active during past 2 years, records in the State Department of Health show that approximately 500 cross-connections have been investigated in recent years of which number more than 300 have been eliminated. It is also felt that the statewide publicity on this work and the additional momentum gained from the definite position that the U. S. Public Health Service has taken with regard to cross-connections and the resulting recent action of our larger cities are doing much to reduce the cross-connection problem in Texas.—Paper read before the Public Health Engineering Section of the A. P. H. A. at the Fifty-ninth Annual Meeting at Fort Worth, Tex., October 28, 1930.

INDUSTRIAL HYGIENE

EMERY R. HAYHURST, M. D., PH. D., AND LEONARD GREENBURG,
M. D., PH. D.

Sixth International Congress of Industrial Accidents and Diseases—

This Congress which is to be held in Geneva, Switzerland, August 3-8, 1931, is the same as one which met in Budapest three years ago. Representatives have now been named for 17 countries, while several more are expected. For the United States the President of the Delegation is Dr. Francis D. Patterson, P. O. Box 4061, West Philadelphia Station, Philadelphia, Pa., and Correspondents: Professor Emery R. Hayhurst, Ohio State University, Columbus, O., and Dr. Francis D. Donoghue, Medical Adviser, Commonwealth of Massachusetts, Department of Industrial Accidents, State House, Boston, Mass. The balance of the American committee is rapidly being formulated and those interested should correspond with some one of the three above named.

The meeting will be a Joint Congress representing the activities of the Permanent International Committee on Accidents and the Permanent International Committee on Industrial Medicine. The activities have been divided into two sections: A. Surgery, and B, Medicine. The particular subjects so far devised are as follows:

Sections A and B

- I. Cutaneous Affections in Relation to Occupation (Accidents and Diseases)
- II. The Influence of Previous Health on the Results of Industrial Accidents and Diseases

Section A

- III. Sequelae and Final Results of Traumatic Wounds of the Spine
- IV. Traumatism of Blood Vessels (Arthritis and Thrombophlebitis)

Section B

- V. Illness Affecting Men Working upon Cement and Artificial Stones
- VI. Reaction of the Organism toward the Toxic Substances used in Industry
- VII. Fatigue

A certain number of additional subjects will also be dealt with. An exhibition of photographs, radiographs, and plaster casts relating to the subjects of the Congress will be on view at the university. Those who wish to exhibit should get in touch with Dr. Jentzer, 8 Rue de l'Université, Genève.

The three persons above named as heading up the American delegation have been supplied with printed material setting forth in full the details of the Congress and will be glad to dispatch to anyone interested a unit of the material so long as the supply lasts.

The Honorary Presidents named for the Congress are Dr. Kaufmann, Zurich; Professor Devoto, Milan; M. Albert Thomas, Geneva; Sir Thomas Oliver, Newcastle-on-Tyne; and Dr. Pometta, Lucerne. E. R. H.

High Lights of the Medical and Health Program of the Consolidation Coal Company, Inc., Year of 1930—

1. 163,024 individuals received medical attention. 42,768 of these were seen in the homes.

2. 30,837 individual typhoid inoculations were given. 11,002 persons were vaccinated for smallpox.

3. Typhoid fever and smallpox have been practically eliminated and other communicable diseases materially reduced.

4. 5,493 physical examinations were given to applicants for employment.

5. 5,027 occupational injuries were attended, requiring 11,408 subsequent attentions.

6. 835 babies were born; 449 being boys and 386 girls.

7. Total deaths numbered 204.

8. 350 clinics were held with a total attendance of 3,841.

9. 5,709 physical defects were corrected, most of these being dental, nutritional, nose and throat defects.

10. 50 classes in home hygiene were taught, requiring 346 sessions with a total attendance of 4,450.

11. Sanitary inspection committees made monthly inspections of most communities.

12. The "Jenkins" Hospital was accepted and accredited by the American College of Surgeons.

13. This hospital admitted 638 patients for major illness and injury.

14. 350 food handlers were given physical examinations.

15. Water and milk supplies were followed up by monthly inspections and laboratory examinations.

16. Regular monthly medical staff meetings were held in the larger divisions.

17. Hundreds of cases were provided with material relief through the efforts of the nurses.

18. Community organizations, such as Parent-Teacher Associations, Girl and Boy Scouts, have been fostered and developed by the nurses.

19. The staff and personnel consisted of 23 full-time, several part-time physicians and 12 public health nurses, coördinating with other agencies, health departments, private physicians and hospitals.

20. Facilities were increased, and program extended with a decrease in cost.—

D. J. Kindel, Medical Director, Fairmont, W. Va., Feb., 1931. E. R. H.

The Physiological Effects of High Concentrations of Carbon Dioxide—From the summary: The subjective and objective effects of toxic concentrations of CO₂ on men were studied, the percentages varying from 5.5 to 12.4 per cent with oxygen ranging from 14.4 to 39.7 per cent.

The concentrations of CO₂ were so excessive as to be tolerated for only a comparatively short time. The periods of exposure did not represent the extreme limit of endurance but a stage was reached beyond which serious symptoms

were impending. The maximum period of exposure was 22 minutes at 6 per cent and the minimum 1/2 minute at 10.4 per cent CO₂.

The respiratory rate per minute showed a tendency to a slight increase above normal; the pulse rate was accelerated in moderate degree; the systolic blood pressure always increased and rose with ascending CO₂ concentration—at 6 per cent CO₂ the increase was 18 m., at 10.4 per cent it was 52 m. and at 12.4 per cent 97 m. maximum; the diastolic blood pressure showed in general a trend similar to that of the systolic pressure; the average minute-expiration volume increased as follows: 203 per cent at 6 per cent CO₂, 225 per cent at 7.5 per cent, 228 per cent at 8.8 per cent, 279 per cent at 10.4 per cent, and only 153 per cent at 12.4 per cent CO₂. The last-named result is of particular interest, as it indicates a fall in the lung ventilation at this concentration of CO₂, whereas there was an increase up to and including 10.4 per cent CO₂. There were wide individual differences between subjects, as was observed in the other physiological responses.

The subjective symptoms were as follows: marked dyspnea resembling the effect of extreme physical exertion, dizziness, flushing and sweating of the face, feeling of stupefaction and an apprehension of impending collapse. The after-effects were practically limited to moderately severe headache but not persisting beyond 30 minutes. There was marked individual variation in the severity of the symptoms, certain subjects showing much less intolerance to high concentrations of CO₂ than others. It is not believed that any of the subjects could have withstood 10 per cent CO₂ for longer than 10 minutes without losing consciousness.

There was no evidence that high oxygen alleviated the toxic effects of the excessively high concentrations of CO₂ em-

ployed in these experiments.—E. W. Brown, Commander, Medical Corps, U. S. N., *U. S. Nav. M. Bull.*, 28, 4: 1930, 13 pp. ill. E. R. H.

Report, Division of Industrial Hygiene, Ohio Department of Health—This is a brief but comprehensive report of the Division's work which is divided into two parts, the first covering the period from July 1, 1915, to December 31, 1928, and the second for the calendar year 1929. These are the first printed reports summarizing the activities of the division's work for 15 years, due to the lack of funds for publishing same. As it is, the two respective reports are contained in a single volume which also encompasses the reports of all the divisions of the State Department of Health, both for the 14-year period and for the year 1929, within a total of 406 pages, including tables, graphs, and illustrations. Necessarily the material is therefore very compact and there is evidence throughout the volume of great thought being given to saying much in few words.

The 14-year report of the Division of Industrial Hygiene concerns the early history of the subject of industrial hygiene in the state, beginning in 1886, the names of the chiefs of the division since it was founded May 15, 1913, the major investigations made, the relation of the matter of compensable diseases to the Industrial Commission as well as the Department of Industrial Relations; the prime functions of the division; a table summarizing all of the occupational diseases reported to the division since it was established in 1913—a total of 10,761 case reports; and a summary of carbon monoxide poisonings occurring in the state and officially reported, these being chiefly of domestic origin.

The 1929 report of the division concerns its present personnel, its main activities during the year, and a table showing an analysis of the 1,411 case

reports of occupational diseases received during the year. Of these, 1,305 came under the *compensable* list under the state law while the *non-compensable* group was composed of 37 reports due to *specific agents* (chiefly poisons), 33 reports composed of various bodily *afflictions* (the agents not specified), and 36 reports which were regarded as *acute accidental*, i.e., due to single or limited exposures, and therefore not classifiable as occupational "diseases."

Another table analyzes the industrial sources of 183 cases of *lead poisoning* reported during the year, of which 5 were among females; another table presents an analysis of 985 case reports of industrial *dermatitis*, classified according to offending agents—the chief ones being oils and cutting compounds (197), rubber (179), benzine, gasoline, naphtha (47), plating solutions (54), "formica" (39), lime and cement (28), acids (35). Reference is made to an exhaustive study of *silicosis and tuberculosis* in the sandstone quarries of Lorain County which was started in 1926–1927 by Dr. Hayhurst and Dr. Kindel and was completed by the present personnel of the division and Dr. C. D. Barrett, health commissioner of Lorain County, and published in the *Journal of Industrial Hygiene*, September, 1929. Here, 919 workmen were stereoradiographed with a finding of pulmonary pathology in 55.1 per cent, including 28.5 per cent with silicosis in various stages. The total tuberculosis was, however, but 1.9 per cent. Likewise general disability was low. These findings checked relatively closely with those of the tuberculosis statistics for the community. The period for developing silicosis, namely, 16.24 years, was over twice that reported elsewhere. The rock was found to have an average content of from 92.15 to 97 per cent crystalline silica (SiO_2).

Likewise, an investigation of 32 cases of *occupational lung diseases* occurring

among sandblasters, emery grinders, stonecutters, and pottery men, is reported upon briefly.

Tables of domestic *carbon monoxide poisoning* mishaps, which are required to be officially reported in the state, are likewise presented as well as a list of the more intimate duties of the personnel of the division, of special trips made, notable persons visiting the division during the course of the year, chief publications made, radio talks, special lectures, etc.—Byron E. Neiswander and Emery R. Hayhurst, *Thirty-First Report (43d year), Ohio Department of Health*, 1931, pp. 188–195, 373–382. E. R. H.

Poisoning by Hydrocyanic Gas—

The annotation is based upon the article by Professor Joseph Barcroft in the *Journal of Hygiene*, January, 1931, page 1. It was found that the relationship between the concentration of hydrocyanic gas and the duration of exposure to it is not a simple one. The size of the animal was also found to be no criterion of its ability to survive, although when the total amount of HCN inhaled by each animal was calculated, it was found to be the same when the total ventilation rate of two animals like the cat and the rabbit was considered. Thus the concentration of HCN would be the same in the blood of both animals when death occurs. "The toxicity of the poison is due to its paralyzing effect upon intercellular oxydases, and the respiratory center is the earliest of the vital tissues to succumb. Canaries and pigeons are much more susceptible than rats and mice."

An actual experiment was made where "a man" and a dog were both enclosed in an airtight chamber, the atmosphere of which contained HCN at a concentration of about 1 part in 1,800. The dog became unconscious in 1½ minutes, while the man felt no symptoms. It is known also that mice and canaries

are more easily killed than the dog, and for this reason the mouse is sometimes used for testing the toxicity of an atmosphere. Here, however, a fallacy may arise since the observer who carries the animal into a suspected atmosphere is performing work, whereas the mouse may be at rest so that its relative sensitiveness is diminished. Where the concentration of the gas is low (0.1 mg. per litre) the best indicators are birds. A man could breathe this atmosphere for 10 minutes without harm, whereas canaries would be dead in 2 minutes. Precautions must be taken by the observer, however, not to exert himself unduly.

In regard to treatment artificial respiration and injection of glucose have been proposed. The latter was found, however, to have no protective action. Since the heart may go on beating for some time after respiration ceases, the greatest hope for recovery seems to lie in artificial respiration. This will also assist in dissipation of the HCN, and, if oxygen be used instead of air, it seems natural to assume that the dissipation of the toxin will be hastened.—*Lancet* (London), 5607: 362–363 (Feb. 14), 1931. E. R. H.

The Value of High Oxygen in Preventing the Physiological Effects of Noxious Concentrations of Carbon Dioxide—The following is taken from the summary of this illustrated reprint of 31 pages, including bibliography:

The two objects of the present investigation were to determine the following: (1) The influence of high oxygen on the noxious effects of high carbon dioxide in submarines and (2) the effect of high concentrations of carbon dioxide on physical and mental efficiency. The term high oxygen in these experiments signifies the maintenance of approximately normal oxygen under conditions of rebreathing in a closed space.

A total of 11 persons served as subjects of the tests, 4 being ordinarily designated for each experiment. The duration varied from $5\frac{1}{3}$ to 12 hours, the average approximating 8 hours. The subjects were not aware of the air conditions, thus eliminating the psychological factor in connection with the effect of oxygen.

Where the final carbon dioxide ranged from 4.7 to 5.2 per cent and the oxygen from 17.8 to 15.5 per cent (the oxygen being gradually reduced by rebreathing in proportion to the rise of carbon dioxide), no effects on breathing were noted at 2 per cent carbon dioxide except on exertion. The subjects in general were not definitely conscious of increased respiratory effort at rest until approximately 3.5 per cent was reached.

At the close of the tests of this group, slight depression, headache, chilliness, and fatigue were the chief symptoms, while body temperatures were subnormal, breathing was labored, but there was no feeling of actual dyspnea with carbon dioxide below 5 per cent.

A group of four tests was conducted in which the final carbon dioxide varied from 4.3 to 4.7 per cent and oxygen from 18.2 to 23.4 per cent. Here the subjective symptoms appeared to be somewhat less but the differences were not clear-cut. The depth and rate of breathing were not influenced.

It is not considered advisable to expose subjects to concentrations higher than 6 per cent of carbon dioxide where oxygen is not supplied.

Headaches persisted for 1 to 3 hours following the tests, but there was a wide individual variation in the type and severity of symptoms. Chilly sensations were general with a final body temperature of 1° to 3° F. subnormal. Persistent fatigue subsequent to the tests was an outstanding symptom.

An air combination of low oxygen and low carbon dioxide was also set up. Initial symptoms of oxygen depletion were noted between 13 and 14 per cent of oxygen, but no signs were manifested with oxygen between 14 and 15 per cent with low carbon dioxide, but the train of symptoms associated with 5.8 per cent of carbon dioxide and 14 to 15 per cent of oxygen were severe and were lessened to a considerable extent when oxygen was kept at the normal level.

Army Alpha cancellation and addition tests were carried out at successive intervals. The functions of attention, memory, association and deduction were involved. The results were striking in that the psychological effects were slight.

It is felt that the personnel could carry on their usual submarine duties for a protracted period, if carbon dioxide did not exceed 5 per cent, but it is believed that the majority would be completely incapacitated where carbon dioxide was above 6 per cent, which is regarded as the critical point. "The supply of oxygen would improve physical and mental efficiency between 5 and 6 per cent of carbon dioxide but would not prolong it beyond the latter figure."—E. W. Brown, Commander, Medical Corps, U. S. N., *U. S. Nav. M. Bull.*, 28, 3: 1930. E. R. H.

Workmen's Compensation Law and Industrial Board Rules—This 155-page pamphlet discusses in great detail the amendments, additions and annotations to the New York State Compensation Law up to November 1, 1930. It is impossible to present any detailed review of this pamphlet, except to point out that it is a mine of valuable information concerning the New York State Law and its interpretation.—New York State Dept. of Labor, Bureau of Statistics and Information. L. G.

FOOD, DRUGS AND NUTRITION

WALTER S. FRISBIE

A New Factor in Nutrition—In feeding a concentrated product of B vitamins to rats on a vitamin-B free basal ration, it was noted that the hair of both the black rats and the black and white rats became silver gray, different in appearance from the result of anemia and without reduced hemoglobin. While rats appeared to be healthy, they were subject to xerophthalmia although there was no deficiency in vitamin A.

Reproduction was abnormal, some remaining sterile and others giving birth to litters which did not live. The material was given in greater amounts than is indicated for vitamin B sufficiency. With the addition of yeast to the diet, the discoloration of hair was observed in some cases but not in others. The material in question was supposed to be wheat germ from which the toxic elements had been removed. The introduction into the diet of wheat germ oil extracted either with acetone or ether did not prevent the hair from turning gray. Obviously removing impurities from germ oil also removed liposoluble vitamins. It is noted that this oil has been eliminated as a result of American experimenters who report toxic conditions. The authors comment that the doses were probably large enough to be harmful but in their series no adverse effects were noted with ordinary doses.

Subsequently, various alimentary meals were added which contained whole wheat as the base. In all cases, the rats without exception assumed the normal color of the hair. One group of rats was given whole wheat grains and the second the separated germ. In the

first case, the hair remained black, and silvered in the second, and in the latter case the hair assumed its normal hue with the addition of whole wheat to the diet. In all these cases with discoloration of the hair symptoms resembling xerophthalmia appeared which were not cured by cod liver oil.

It is believed that the toxic element in the wheat germ is counterbalanced by substances in the entire wheat. However, if the special product or wheat germ solely is administered for a sufficient length of time, the hair color returns to normal; the animals practically acquiring an immunity to the toxic substances. These experiments were performed on a large number of animals and are to be continued.—A. Bakke, V. Aschehoug, and Chr. Zbinden, *Compt. rend. Acad. d. sc.*, 191: 1157 (Dec. 8), 1930.

Digestion; Efficiency with Various Foods and under Various Conditions—This work represents an extension of the study by Hosoi, Alvares, and Mann (*Arch. int. Med.*, 41: 112, Jan., 1928), on Intestinal Absorption, particularly the effect of finely divided food and artificially retarded peristalsis. The work was performed on dogs after removal of the colon. The efficiency of the digestion was based on the moist weight of the food intake compared to the moist weight of the feces.

Both milk and sour milk were digested when given in large amounts. Residues in the former were 33 to 54 per cent, and in the latter 18 to 25 per cent, indicating better digestion with sour milk.

Cottage cheese was well digested but

impaired the digestion of food given the following day. The same effect was also observed with lard and lacto:c. Meat was better digested when fed in lumps than when comminuted and the same was true of potatoes. Raw meat was better assimilated than cooked meat. With fat, 10 gm. for each kg. of body weight appeared to be the limit. Raw egg albumin was practically undigested. Soft boiled and hard boiled eggs digested better, soft boiled eggs leaving the smallest residue. When raw egg was added to raw starch, the digestion of egg was improved, the residue of the mixed food being considerably less than the residue from either food alone.

Bread residues which were large were lessened when milk or coffee was given with the bread.

Cooked vegetables, such as potatoes, tomatoes, bananas, prunes, corn and peas, gave large residues, indicating poor digestion. Rice was almost perfectly digested. Relatively large residues were the result of feeding fruit juices, accounted for by the rapid passage through the bowel.

Forced feeding apparently had no effect on the amount of fecal residue. Excitement or anxiety in the case of one dog showed a residue of 77 per cent of the amount ingested, and when quiet, the figure dropped to 41 per cent in the case of the same dog. Heat and cold apparently had no effect.

The authors believe these studies will be a benefit in the treatment of humans requiring special diets; particularly noteworthy is the increased digestibility in combinations of foods neither of which is well digested alone, and the further effect of such substances as fats on the digestibility the day following ingestion. The experiment further revealed the fact that food taken in one large amount is better utilized than in several fractions at intervals. Frequent feedings stimulated peristalsis, causing the food to pass too rapidly. Purgatives

and sodium bicarbonate interfered with digestion, again of interest in human cases, making it difficult to tell whether the disturbance is due to purging or to a disease.—John H. Childrey, Walter C. Alvarez, and Frank C. Mann, *Arch. int. Med.*, 46: 361 (Sept.), 1930.

Chemicals Added to Flour—In many parts of France, complaints have been made because of the inferior quality of the bread. The complaints doubtless in part date from the war period, when the scarcity of wheat made necessary the addition to wheat flour of flour derived from other grains or from legumes. In some instances the bakers have continued this practice, as it increases the profits. Some even add powdered minerals to increase the weight of bread.

Successive decrees have restricted the authorized use of flours other than wheat flours to the periods when there is a deficiency of wheat flour, which does not obtain at present. A decree dated November 7, 1930, prohibits the addition of any mineral matter that is not authorized by the superior council of hygiene. This decree was aimed particularly against the salts used to bleach gray flour and to facilitate bread making.

The council of hygiene has recently authorized the use of such substances as are employed only to promote the action of the yeast; namely, potassium bromate, at the rate of 2 mg. per 100 gm. of flour, which constitutes 10 mg. of bromide per kg. of flour, a negligible quantity, and even less than the amount contained in ordinary table salt; and ammonium persulphate, at the rate of 3 mg. per 100 gm. of flour. Sodium perborate, much used in the past, has been prohibited.

It has been stated that the reasons for the acceptance of these substances are that they facilitate the action of the yeast and the rising of the dough, and,

in addition, make it easier for the baker to prepare the yeast when French wheat is used.

Messrs. Desgrez and Bonn of Paris and Mr. Laborde of Strasbourg performed experiments on guinea pigs for 2 months, using wheat that contained the permitted quantities of bromate and persulphate. The animals thus fed developed as well as the control animals and exhibited no changes in their organs.—Paris Correspondent, Dec. 17, 1930, *J. A. M. A.*, 96: 282 (Jan. 24), 1931.

A New Cereal Mixture Containing Vitamins and Mineral Elements—It has been stated that cereal grain furnishes 30 to 60 per cent of the calories of the average diet. Since they are consumed largely for their energy-producing value, they constitute a most important part of the daily diet. Whole grain cereals are deficient in many of the minerals and in all of the vitamins. In view of this fact, a cereal mixture composed of wheat meal, oat meal, corn meal, bone meal, wheat germ, dried brewer's yeast, and alfalfa, has been devised which, in addition to supplying energy, furnishes the necessary minerals and 5 of the 6 known vitamins.

Vitamin A is obtained from the wheat germ, and the alfalfa, vitamins B₁ and B₂ from the wheat germ, and the brewer's yeast, vitamin D from the irradiation of the wheat germ or yeast, and vitamin E from the wheat germ. The minerals are obtained from the bone meal, wheat germ and alfalfa, 3½ oz. of cereal containing as much calcium as 22 oz. of milk. The iron content is almost twice that of egg yolk, while copper is present in good concentration, 1.3 mg. per 100 gm. of cereal.

The mixture has been used almost exclusively in the Toronto Hospital for Sick Children, an institution containing over 300 beds. It is as palatable as the finely milled cereals now so widely used

and should prove a valuable addition to the diet, because of the many elements contained therein which are known to be essential for normal nutrition.—Frederick F. Tisdall, T. G. H. Drake, and Alan Brown, *Am. J. Dis. Child.*, 40: 791 (Oct.), 1930.

Commercially Prepared Infant Foods—In recent years there has appeared on the market a number of proprietary compounds for use in infant feeding. There are four groups of these commercially prepared foods and this paper describes the different groups.

The first group includes the so-called "reconstructed" baby food and is made up generally of powdered milk, cod liver oil and sugar, in addition to the milk sugar already present. These foods meet all the recognized food requirements of babies.

The second group is the so-called "milk modifier." While the milk sugar normally present in milk may be available for digestion by the baby, physicians feel that another sugar which can be assimilated quickly should be added in certain cases. For this reason, compounds have appeared on the market as "modifiers."

Another group is "protein milk." This has been designed for infants who have developed certain temporary complaints, particularly diarrhea.

The third group is "lactic acid milk." The use of this milk, which is made up of cows' milk to which has been added chemically pure lactic acid or the milk allowed by culture to develop its own lactic acid from the milk sugar, allows the baby to adjust itself to the diet of the cows' milk.

The fourth group is the powdered, evaporated and condensed milk. These brands are used by many mothers for older babies due to the conveniences of handling.

No attempt has been made in this

study to discuss the merits from a nutrition standpoint of the different brands of infant food on the market, and before adopting such infant foods, the mother should consult a physician as to the type of food essential and adapted to the particular infant.

The mother has a right to demand that these infant foods should meet the highest sanitary standards, which include the following:

1. The infant food should be produced under clean conditions and kept clean throughout its journey through the processing plant to the baby.

2. There should be no harmful bacteria present.

3. The number of bacteria present should be reduced to a minimum.

It is understood, from examination of a number of samples, that practically all of the infant foods now on the market meet these standards.—G. J. Hucker and Alice M. Hucker, *New York State Agri. Exper. Sta., Bull. 584* (Oct.), 1930.

Effect of Drying and Sulphuring on Vitamin C Content of Prunes and Apricots—There was previously reported the result of studies made on

vitamin C of peaches (abstract, this JOURNAL, 19: 1053, Sept., 1929, and 20: 1362, Dec., 1930). The present paper reports the effect of drying and sulphuring on the vitamin C of prunes and apricots. The fruit was prepared as in the previous experiments. A table is given showing the composition of the fruits tested.

Guinea pigs were used as test animals and they were fed doses of the different fruit products for 60 to 90 days. At the end of the 90 days, autopsy was performed on all animals and examination made for symptoms of scurvy. The 60-day period was found to be as effective for assay of vitamin C as the 90-day period. Both the dehydrated prunes and apricots retained vitamin C more completely than did the sundried. The dehydrated and sundried apricots containing 450 to 500 or more p.p.m. of sulphur dioxide retained the antiscorbutic property more or less completely. With a less amount, this property was lost entirely. All of the unsulphured fruits whether dried or dehydrated had no antiscorbutic value.—Agnes Fay Morgan, Anna Field, and P. F. Nichols, *J. Agri. Res.*, 42: 35 (Jan. 1), 1931.

CHILD HYGIENE

RICHARD A. BOLT, M. D., DR. P. H.

IT was indicated in last month's JOURNAL that education for parenthood should really begin in our secondary schools where it can be correlated readily with home economics and science, as well as with other subjects. In the tentative report¹ prepared by the late Anna E. Richardson, Chairman of the Sub-Committee on Education for Home and Family Life, of the White House Conference on Child Health and

Protection, the importance of well planned courses in these subjects is stressed. A number of progressive high schools throughout the country have already incorporated such courses in their regular curriculums. Where these can be combined with actual observation of young children, and opportunity given to assist in their care, there is every reason to believe that considerable good will result.

But such instruction in the schools is not enough. It must be continued with greater emphasis into the parental period. Courses along the line of parental education are now offered in many university extension centers, and numerous organizations, among them Parent-Teacher Associations, Federations of Women's Clubs, etc., are taking an active interest in this work. Popular magazines and newspapers are publishing articles featuring maternal and infant care.

Literature published by the U. S. Children's Bureau has reached to every corner of this country. Its pamphlet on Prenatal Care,² published in 1913, written originally by Mrs. Max West, and recently completely revised by an advisory committee on obstetrics, has undoubtedly had the widest circulation of any material of this type, distribution reaching into millions of homes.

The revised edition has been brought up to date and is more attractively illustrated. It is simply written, authoritative, and appeals to the interests of mothers and prospective mothers. Health officers would do well to give this prenatal educational brochure wide distribution.

The Maternity Center Association of New York, after a thoroughgoing demonstration of what can be accomplished in maternal hygiene, now proposes a new use for Mother's Day, with the practical purpose of pointing out the dangers to which motherhood is exposed, and bringing to the attention of the laity and medical profession alike the possibilities of reducing the altogether too high maternal and early infant mortality in this country.

A nation-wide campaign of educational publicity is to be conducted with emphasis upon a study of the local maternity needs, and possibilities for bettering conditions. In setting forth this program, Dwight S. Anderson³ has the following to say:

Mother's Day—May 10—will signalize a national educational movement to direct the attention of the American people to our deplorable maternal death rate, said to be the highest in the civilized world. It is hoped to make Mother's Day this year mark the beginning of an attempt to get adequate maternity care for every expectant mother.

Mother's Day seems the opportune time to direct attention to this subject. As the appeal is planned to be entirely educational, without any features of money raising whatever, it is felt that people will welcome a constructive use of this occasion—a new Mother's Day wholly without commercialized propaganda. Endorsements were given by Surgeon General Cumming of the U. S. Public Health Service and Grace Abbott of the Children's Bureau. The coöperation of women's clubs was obtained through the endorsement of Sadie Orr Dunbar, Chairman of the Welfare Division of the General Federation of Women's Clubs.

While national publicity⁴ is planned, including radio talks, news stories, as well as display advertisements and articles in magazines, trade journals and house organs, dependence for results rests principally with local clubs and health groups which are to engage in the campaign. Such organizations are to be assisted in promoting a local campaign in their own names, using ideas and suggestions which will be sent interested persons.

In order effectively to draw public attention to the need and importance of adequate maternity care, those interested in community efforts are urged, during the week or two before Mother's Day, to familiarize themselves and their professional associates with the local maternity situation; that is, the number of births, the number of doctors, the number of midwives, the number of hospital beds for maternity patients, the available nursing and home help services, the number of mothers who die having babies, the number of babies who do not live a year, the number who are born dead. How early in pregnancy do mothers come under medical care and does that care continue until the baby is 6 weeks old?

It is suggested that Mother's Day publicity efforts include:

1. Newspaper stories, concerning local and national maternity work. Interviews with a prominent obstetrician or laywoman; homely interesting items by the president of the Hospital Board or the local director of any Health or Nurses' Association.

2. Editorials. Editors of papers, whether city or country, daily or weekly, should be requested to comment editorially on the above material.

3. Proclamation from the local Health Officer should be obtained, endorsing such observance of Mother's Day as will result in improved maternity care.

4. Announcements by pastors of Mother's Day and its observance in a modern enlightened way, calling attention to whatever meeting has been planned.

5. Educational literature for mothers and fathers.

Articles, stories, advertisements, suggestions for editorial comment, and educational literature for mothers and fathers can be obtained from the Maternity Center Association, 578 Madison Avenue, New York, N. Y., free of charge.

This endeavor is to be highly commended, but it is hoped that it is just the beginning of a concerted effort to extend the routines and technics already so well worked out by the Maternity Center Association. Furthermore, it seems that here is an opportunity to give widespread publicity to the findings of the Sub-Committee on Prenatal and Maternal Care, of the White House Conference.

It would be enlightening to secure the opinions of the state bureaus of child hygiene which have sent out prenatal letters to prospective mothers in their states. These letters, in one form or another, have been widely used a decade or more, and some of the states continue to use them. Where they have been prepared with the coöperation of the local or state medical societies and used by the doctors in their private practice one would expect a noticeable amount of good to have resulted. Where these letters can be followed up by the instructions of public health nurses, and by repeated examinations by physicians, either in their own offices or in prenatal centers, the maximum good can be accomplished. Visiting nurses in some of our larger cities have already shown what can be done along these lines. Another avenue of approach which has been tried but little is the sending of one of the booklets on prenatal care to all newly married couples, the names

being obtained from the marriage register clerk. This would call attention to the importance of getting in touch with a capable physician as early in pregnancy as possible. Physicians should also have a supply of simply worded pamphlets which can be given to their regular patients.

A method of prenatal instruction which has proved valuable is group instruction in the prenatal centers or in clinics where patients are waiting for the physician. This has been done in Cleveland for the past 4 years in connection with the Maternity Hospital and its 7 prenatal centers, and in 3 of the other hospitals. An experienced and well trained public health nurse is employed to conduct the classes in the various centers. She early prepares a set of lesson sheets on the most important points in prenatal care, which the physicians connected with the hospitals approve before they are put into use. Her method is a simple direct approach to practical every-day problems and answering any questions which arise. This work is supplemented by group instruction, conducted by a trained nutritionist who carries out actual demonstrations in preparing suitable foods. It not only occupies the time which might otherwise be taken up by gossip among the patients, but gives them useful suggestions and educates them to appreciate the value of good prenatal care. During the past year over 3,000 mothers and prospective mothers were reached by this group instruction, and of this number only 1 maternal death occurred. This type of instruction, coupled with visual education in the waiting room, should do much to make the physician's work easier and result in better follow-up on part of physician and nurse.

Every hospital which accepts maternity cases should make ample provision for thorough prenatal service. This is relatively easy for the exclusively maternity hospitals, with a closed staff,

especially when under university auspices. But it is much more difficult where the maternity work is simply part of a general hospital service, and open staff arrangements prevail. Here it is difficult to standardize the routines and to get the individual physician's patients under proper prenatal care early enough in pregnancy. We should strive to bring about the organization of a prenatal service in such hospitals, however, as an extension of the regular nursing and social service departments.

It is enlightening to study intimately the results of obstetric service in a number of the hospitals of a large city. One is immediately struck with the great difference in maternal and early infant mortality rates in the different hospitals. While the causes back of this may be complex, in many instances it is readily discernible that the hospitals making ample provision for careful prenatal care and instruction, and having a proper control over obstetric routines, exhibit the lowest mortality. If the local health authorities should compile each year a list of local hospitals showing the number of obstetric beds in each, the total live births, stillbirths, and deaths under 2 weeks, together with the maternal deaths, it would afford a basis for comparison which would be very salutary and indicate places where improvements could be made.

Advantage should be taken of every occasion to bring before the whole community the problems of maternity and infancy. For the past few years Child Health Day—May Day—has afforded such an opportunity. This has been taken advantage of in a number of states. Among those which have carried on consistent and widespread health education Indiana ranks high. Last year Indiana had a well planned program for Child Health Day, with radio talks and a general meeting attended by

representatives of all the health interests of Indianapolis. This year plans are already under way for the May Day celebration. A very attractive mimeographed program⁶ has been prepared which contains definite suggestions as to how this day can be used throughout the state for educational purposes.

The *Eighteenth Annual Report of the Chief of the Children's Bureau* is replete with information relating to the work of the bureau for the year ending June 30, 1930. It discusses the final work in connection with the administration of the Maternity and Infancy Act of 1921 and reviews pending legislation for maternity and infancy. The Senate Bill Number S. 255, which it mentions, was amended by the House Committee on Interstate and Foreign Commerce⁶ to provide for a county health unit organization to promote general health measures as well as for a special maternal and child health program. The amended bill was reported favorably out of Committee and passed the House of Representatives a few days before adjournment. It was placed on the Senate Calendar for action but failed to pass on account of a filibuster which developed in the closing hours of Congress. The proponents of the bill undoubtedly will revive it in the new Congress which meets next December.

PUBLIC HEALTH NURSING

EVA F. MACDOUGALL, R. N.*

Public Health Nursing in Alberta and Saskatchewan—Public health nurses are employed in three rural municipalities in Alberta. Half their salaries are paid by the municipalities, half by the Province. One nurse demonstrates home nursing and first aid at the request of local organizations and is in great demand. Child welfare stations in Calgary, Edmonton and Medicine Hat are in charge of public health nurses.

Seven district nurses are stationed in frontier communities, mostly in the northern part of the Province where there are no medical or hospital facilities of any kind available. These nurses are very carefully selected and are required to have special obstetrical training. They provide special service in midwifery, bedside nursing, child hygiene, first aid and the like.

In the summer several public health nurses travel through the Province with a Travelling Child Welfare Clinic. Local physicians are invited to coöperate in the conferences arranged by local organizations. These conferences are attended mostly by preschool children who are weighed, measured and inspected, and mothers are advised with reference to diet and correction of defects.

In Saskatchewan the Victorian Order of Nurses has placed one of its nurses in each of three rural districts as an experiment. They do bedside nursing similar to that done in urban centers. The Victorian Order pays their salaries

and supervises their work; each municipality gives a grant to the V. O. N. and patients pay a nominal fee when they can. Each nurse is supplied with a car by the Department of Health. The hope is that when a demonstration has been made the municipalities will carry on the work entirely at their own expense.

There are 14 government nurses located in various parts of the Province. One of these nurses serves all maternity cases in one municipality at the expense of the local municipal government, and in a period of 6 years there were 185 births and no maternal deaths. In the same period the infant mortality was 48.7, and not one death from a communicable disease occurred.

Another New Course in Public Health Nursing—A Department of Public Health Nursing was opened at Syracuse University in February, 1931. Ellen L. Buell, R.N., formerly Educational Director of the Henry Street Visiting Nurse Service, New York, N. Y., is director.

The length of the course is approximately one college year and one summer session totalling 36 credit hours. A certificate of Public Health Nursing is to be granted by the College of Medicine of the University. If nurses are interested they may write to Miss Buell for the bulletin describing the courses of study.—Abstracts from Preliminary Announcement of Course.

Measles Conference—Public health nurses joined health officers, representatives from the State Charities Aid Association, the State Medical Society and other organizations in a general conference on measles in Albany in January, arranged by the New York State Department of Health.

The conference conceded that measles cannot be prevented but that much can be done to decrease the number of complications which often prove fatal. The following important facts were emphasized:

1. The disease should be postponed until after the 3d and better until after the 5th birthday.

2. Adequate medical, nursing, and hygienic care are the most important means of preventing complications and a fatal outcome.

3. The disease is particularly fatal among undernourished and underprivileged children, and unusual methods of control must be applied to prevent or ameliorate the disease in such children.

The conference agreed that public health nurses could best be used in preventing measles:

1. By discovering other unreported cases of children who have been exposed and whose families have not been instructed.

2. By instructing families how to make the best use of available facilities. This should extend to actually demonstrating how to prevent complications through the isolation of the case, choosing the right room, securing proper ventilation and adequate light, cleanliness and orderliness of surroundings, and care of the patient.—

Health News, New York State Dept. of Health, VIII, 5: 19, 20 (Feb. 2), 1931.

More about the Health Officer and the Public Health Nurse—There may be several groups of public health nurses working in a community, one employed by the board of health, another by the visiting nurse association, and the other by the school health department, but if each nurse looks upon herself as a part of a larger group working for the whole community there will be no trouble in

defining what the relationship should be of the different groups to each other and to the health department.

If there are two or more groups of nurses of this kind, however, it is important that they meet together frequently to talk over their problems and become familiar with each other's work. In these meetings also definite plans for special health education programs can be worked out. All the nurses as they visit homes can be on the alert for suspicious cases of tuberculosis, communicable diseases, cancer, etc. Even helpful advice about sunshine and cod liver oil in the prevention of rickets can be given mothers instead of leaving it all for the infant welfare nurses.

Dr. Denny says:

The first thing to do is to decide on what special phases of health work to concentrate. There probably should not be more than three or four different lines of health propaganda to be carried on at any one time and these might be changed from time to time. These could best be decided on by the whole nursing group in conference with the health officer and others familiar with conditions in that community and would vary in different places.

At the present time it would be wise almost everywhere to work at diphtheria immunization. If this were to be done, I would suggest some such procedure as this: Each and every nurse on her visits should inquire whether all the children have been protected. If they have been, a word of commendation is in order. If they have not been, and there is a marked attitude of hostility, it is probably best at first not to say much more than enough to show that the nurse and the organization she represents think favorably of it. Above all, the nurse should not start an argument and force the parent to take a position she will continue to try to defend. At the next visit tell how many children have been treated at the school her children attend or at the nearby health center. Most people hate to be with the minority. They follow like sheep what most of the flock are doing. At a subsequent visit, if still resistant, it is well to speak of some definite case of diphtheria, preferably in the neighborhood, and some family that the mother knows about, where the parents had been meaning to protect the child but had neglected to do so and

now are full of regrets. It is very uncomfortable for us parents to think how we are going to feel if our child gets a serious disease which we might have prevented.

A carefully planned procedure like this just outlined gradually overcomes what is called in the commercial world "the sales resistance" and you finally sell your proposition. The important thing is not to fire all your guns at once but by subtle repetition and by different methods of approach gradually to get the lesson across. With all the nurses in the community, working at the same time for the same object, I am convinced that an astonishing amount could be accomplished.—

Francis P. Denny, M.D., The Relationship of the Nurse to the Health Officer Group, *The Commonwealth*, Massachusetts Dept. of Health, 17, 4: 175-177 (Oct.-Nov.-Dec.), 1930.

Walter Burns Saunders Memorial Medal—The second award of the Walter Burns Saunders Memorial Medal for an outstanding service to nursing will be made this year. At the biennial convention of 1930 the first medal was awarded posthumously to S. Lillian Clayton, former President of the American Nurses Association.

Distinguished for Service in the Cause of Nursing—These words below the name of the recipient mark this medal which is given by W. L. Saunders II, of Philadelphia, in memory of his father, William Burns Saunders.

The recipient to whom the reward will be made must be a member of the American Nurses Association, who has made to the profession or to the public some outstanding contribution either in personal service or in the discovery of some nursing technic that may be to the advantage of the patient and to the profession. The only kind of service excluded is that of writing.

Recommendations should be submitted to the Headquarters of the

American Nurses Association, 370 Seventh Avenue, New York, N. Y., before April 6, 1931.—Walter Burns Saunders Memorial Medal, American Nurses Association Release, Jan., 1931.

The French and German of It—
As nursing activities have developed in the different countries of the world, much confusion has ensued because each country had a different term for the same worker or type of work. Consequently the Nursing Division of the League of Red Cross Societies in collaboration with the International Council of Nurses, after studying the idioms most commonly used, and classifying them, have thus recommended the French and German translations for many hospitals, nursing and social work terms. We are giving four of these terms which might be of particular interest to public health nurses:

<i>French</i>	<i>German</i>
<i>Social Worker</i>	

Assistante sociale; travailleuse sociale; auxiliaire sociale	Fürsorgerin, Sozialarbeiterin
--	----------------------------------

<i>Trained (General) Nurse (Graduate Nurse)</i>	
---	--

Infirmière diplômée	Staatlich anerkannte Krankenpflegerin; ausgebildete Krankenpflegerin; geprüfte Krankenpflegerin; ausgebildete Schwester
---------------------	--

<i>District Nurse</i>	
-----------------------	--

Infirmière visiteuse	Gemeindeschwester
----------------------	-------------------

<i>Public Health Nurse</i>	
----------------------------	--

Infirmière visiteuse; infirmière d'hygiène sociale	Wohlfahrtspflegerin; Fürsorgeschwester
--	---

Nursing Phraseology, *Information Bull.*, League of Red Cross Societies, IX, 11-12: 344 (Nov.-Dec.), 1930.

EDUCATION AND PUBLICITY

EVART G. ROUTZAHN*

Suggestions Invited—"What Everyone Should Know About Cancer," the well done booklet of the American Society for the Control of Cancer, 25 W. 43d St., New York, N. Y., is about to be reissued. There are few high-brow words in it. Can you find one which should be changed? Do you question any statement? Any suggestions to offer Dr. R. V. Brokaw, executive secretary? A copy of the booklet will be sent free upon request.

How About It?—In neighborhoods where there is considerable unemployment could health agencies experiment with "health entertainment" programs? Movies, slides, very brief talks, questions and answers, plays, music? A vacant store? Use volunteers.

Make a fresh attack upon diet at this time?

Tackle "worry"? Boost recreation possibilities?

Try to help present conditions—and *get some of your own job done?*

1931 Publicity Awards—As announced by Social Work Publicity Council, 130 E. 22d St., New York, N. Y., the following will be considered: annual reports, envelope stuffers, house organs for the public, staff house organs, industrial posters, published educational photographs, social case work stories, suburban publicity. Closes April 15, 1931. Many of past awards have gone to health organizations. Any member of S. W. P. Council will have full details.

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

A New National Medium—"Keeping Up With the World!" is a new department in *Collier's Weekly*, 250 Park Ave., New York, N. Y.—a weekly column made of paragraphs—fact, figures, fancy. Plenty of items possible from the health field, and \$1 is paid for each one accepted.

When It Is New—Then is when the editor wishes to see specimens of all types of your publicity. Will you send samples upon request? Free? For how much postage? Sale price? See editor's address at bottom of this page.

The Research Spirit in Health Education—The following is quoted by *Hygeia* from the committee on research in education of the American Association for the Advancement of Science:

We believe that every normal individual is born with some endowment of the research spirit . . . that this mental habit of learning by self-reliant experiment should be conserved and strengthened from the beginning throughout life.

Is not the questioning, testing, observing attitude—the learning attitude—of immense importance to those who seek to change health habits? Some of the health bulletins do not seem to have changed in all the 10 to 20 years they have been reaching me. Even the paper or type remains the same—and in some cases it is atrocious.

The A. A. A. S. report continues:

We believe that all education from pre-kindergarten age on through the university should have this encouragement of the spirit and habit of research as a main object. . . .

We believe that teaching should be conducted only by those who have the research attitude themselves and have ability to cultivate it in their pupils.

This seems to be addressed not only to the teachers in schools but also to the teachers who use the newspaper, the lantern slide and other mediums. You will want to read "The Scientific Mind" in *Hygeia*, Feb., 1931.

Not What It Once Was—Did you read *Hygeia* once upon a time and did you give it up because it lacked many of the elements of a successful popular health magazine? Then you should look over some 1931 issues. The range of the illustrations has a wide appeal beyond the health content of the articles. Titles and text grow better and better. The armor-plate paper was abandoned long ago. The advertisements look interesting and many of them are good reading. But see for yourself. The American Medical Association is to be congratulated for its faith and persistence in the face of many difficulties.

SCHOOLS AND CHILDREN

This department looks forward to the time when there will be adequate provision in the *Journal* for the interests of schools and teachers in the health field. Likewise in the annual meeting. Neither the Public Health Education Section nor the "Education and Publicity" department of the *Journal* should be depended upon for a halting recognition of this vital place of the health movement. Will not some one get this idea before the powers that control our destinies?

If you are concerned with health in the school you read *Hygeia* as a matter of course. So far as we know no other periodical department carries so much of value to the teacher and the health worker. Along with this should go *Child Health Bulletin* (American Child

Health Assn.), which serves a partly different service. It is not possible in this department to call attention to the particular issues of these periodicals—and it should not be necessary.

Frequent articles on classroom teaching or reports of experiments: *Public Health*, Michigan Dept. of Health, Lansing; *Public Health Nurse*, 450 7th Ave., New York, N. Y.; *Red Cross Courier*, Washington, D. C. *Samples free.*

Material for classroom teaching in: *The Crusader*, Wisconsin Anti-Tuberculosis Assn., Milwaukee; *School Health*, Tuberculosis and Health Society, Detroit; *Child Health*, Oregon Tuberculosis Assn., Portland; *Safety Education*, National Safety Council, 1 Park Ave., New York, N. Y. *Samples free.*

The Feb., 1931, issue of *Journal of the National Education Assn.*, Washington, D. C., contained the 36th article of the series on mental hygiene.

Says a mailing card addressed to physicians:

A health certificate is required of every child entering school. Seven out of 10 need medical care. Take your child to your physician *now* for examination and treatment.

The above is a reproduction of a card put out by Brooklyn Tuberculosis and Health Assn., 293 Schermerhorn St. On the address side one-half of space is given to a letter from the president of Medical Society of County of Kings. The card is 6" x 9".

"Making a School Movie." *Cleanliness Journal*, Cleanliness Institute, 45 E. 17th St., New York, N. Y. *Free.* Making a "movie" (in any school or club) without photography or projection machine. A device good for exhibits—as made by children or adults. "Teaching School Children Health: How Best to Reach Boys and Girls in Different Age Groups," by Dr. Iago Galdston. *Everybody's Health*, St.

Paul, Minn. Feb., 1931. 10 cents. A brief statement of first considerations.

The *Missouri Public Health News* (State Board of Health, Sept., 1930) reports on the Blue Ribbon Baby Health Contest conducted at the State Fair. There were classes for rural and town boys and girls—12 to 24 months, 24 to 36 months, 36 to 48 months.

An educational program addressed to junior and senior high schools is being launched by the American Eugenics Society. Address them at New Haven, Conn.

Health in High Schools—a symposium. National Tuberculosis Assn., 450 7th Ave., New York, N. Y. For everyone concerned with high school health. 40 pp. 5 cents.

Teacher's Inventory of Health Assets. National Tuberculosis Assn. Questions on "The Schoolroom," "The Community" and "The Pupils," with "Progress Chart." "Given as examples of what the teacher should ask in order to know whether her health teaching is carrying over into practice in the schoolroom, the home and the community." Likewise a tool for parent-teacher associations, home bureau workers and others who wish to check back from the community to the school. 75 cents for 100.

"Health—the first objective in Education." Welfare Division, Metropolitan Life Ins. Co., New York, N. Y. Classified list of publications issued by School Health Bureau.

You Have An Square A Lunch—Why? National Dairy Council, 221 N. LaSalle St., Chicago, Ill. 16 pages. A study of classroom-lunchroom health teaching directed by Dr. Lydia J. Roberts, University of Chicago. *Free*. Supplemented by teaching material. 50 cents a set.

Health Bulletin for Teachers. Issues for April, 1929–June, 1930, combined. Metropolitan Life Ins. Co., New York, N. Y. Addresses of publishers and

prices are not given with reading references.

The Health and Cleanliness Chronicle of a Junior High Training School. 30 pages. Dull finished paper. *Free for Junior High Schools*.

"No satisfactory text available" on health education says "A Curriculum for the Professional Preparation of Physical Education for Secondary Schools." In the list of reading references *no prices are given* and the *number of pages is not shown*. A regrettable omission. From California State Dept. of Education.

Health and Physical Education Series—Grades I to III. Ohio Dept. of Education. Foot note and reading lists are uneven, *but the majority give the city as well as the publisher*. Prices for 2 groups of pamphlets. The following is significant:

Commercial advertising material may be secured for health teaching. Care should be exercised that it be attractive and true to fact. Circulars and pamphlets containing a minimum amount of good health material and a maximum amount of advertising should be avoided. Schools cannot afford to be used for commercial advertising purposes.

Cleveland schools are not allowed to use health advertising material without special permission from the board of education. In Dayton such material may be used for classroom purposes although it may not be distributed to the children to take home.

HONORABLE MENTION

To the Commonwealth Fund: for Annual Report for 1930—for the aquatone illustrations, type, paper, and table of contents (the last is difficult to find because it does not follow the title page).

To St. John's Guild (floating and seaside hospitals): for Annual Report with table of contents—with committees and officers listed on 3d and 4th cover pages *as indicated in table of contents*—with pages of half-tones scattered through the many pages listing donors and contributors. New York, N. Y.

RADIO

"The Level of Thirteen-Year-Olds," by William Orton. *Atlantic*. Jan., 1931. "What broadcasting is and might be."

The *New York World* gives the credit to radio:

It has shortened the speeches that the citizenry has to endure. Time was when the chief orator at a public gathering took from forty minutes to an hour and a half to reveal that he had nothing to say; the fact probably had a lot to do with the mounting death rate from nervous diseases. But the radio has changed this. . . . There has been a great deal of condensation, and particularly a mortality among the comical Scots, Jews and Irishmen brought to mind by the opening remarks of the toastmaster. . . . Also, there has been a diminution in the water-drinking, coat-buttoning and for-reply-pausing that used to be such a trial on the patience.

V. W. Marr, chairman of Radio Committee, Publicity Group of Boston Council of Social Agencies, offers the following advice to broadcasters:

To arrive late at the studio is one of the most serious offenses in the radio world. Until the arrival of assigned performers, the program manager is sitting on needles and pins wondering whether the scheduled talent is to arrive. Consequently, all broadcasters are requested to be at the studio at least one-half hour before the time scheduled for their broadcast. They should report immediately to the person in charge of the studio.

Another matter of equal import is overtime. Any person who runs over his allotted time in a broadcasting studio is an unwelcome visitor and his chances of further performances are slight. He not only cooks his own goose, but, in the case of a series, jeopardizes the chance of others to obtain the facilities of the station gratuitously.

It appears that too many of the agencies are submitting stereotyped articles with the assumption that the radio audience is, or will become, interested in their cause. Consequently, agencies are urged to bear in mind the slogan "Entertain and Interest."

The Heart Council of the Cincinnati Public Health Federation reports 500 requests from 33 states for pamphlet copies of radio talks.

Connecticut State Dept. of Health reports a radio listener who was led to substitute a visit to a physician for a dose of salts. The listener was hurried to a hospital for an acute appendicitis operation.

Philadelphia Dept. of Health broadcasts over WFI every Tuesday at 6:45 p.m.

"Devils, Drugs and Doctors," a 15-minute broadcast by Dr. H. W. Haggard, sponsored by Eastman Kodak Co., over Columbia System, Sundays: 8:00 p.m. (E. S. T.), 7:00 p.m. (S. C. T.), 6:00 p.m. (M. S. T.), 5:00 p.m. (P. S. T.). Printed copies free.

The Canadian Social Hygiene Council, Toronto, Can., supplies a series of 30 radio talks on various health topics to 16 stations for local broadcasting. Copies may be secured from the Council.

Copies of radio talks may be secured from State Dept. of Health, Hartford, Conn.; State Board of Health, Raleigh, N. C.; Ohio Public Health Assn., Columbus, O.; Bureau of Health, Rochester, N. Y.; U. S. Public Health Service, Washington, D. C.; Cleanliness Institute, 45 East 17th St., New York, N. Y.

On Feb. 4 was given the 82d of the radio talks on "Your Health" broadcast Wednesday afternoons over WEAf by Dr. Shirley W. Wynne, 505 Pearl St., New York, N. Y., who will supply copies on request.

Whenever the 100th broadcast is reached by the New York State Dept. of Health the series is printed in a neat paper bound volume numbering about 125 pages. The fourth volume of *Health By Radio* has appeared. Many of these talks can be taken over by other states and cities with slight changes.

EDUCATIONAL MATERIAL

Prenatal Care. Children's Bureau, Washington, D. C. Revised "best seller."

Carbon monoxide booklet—both French and English. Provincial Bureau of Health, Montreal, Can.

Management of Cases of Communicable Diseases in Isolation or Quarantine. State Department of Health, Des Moines, Ia. Not at all "official" looking. Heavy paper. Simple line cuts. Need not have used the shiny paper. *Free*.

Sex Education, by Edith D. Dixon. Extension Service, Rutgers University, New Brunswick, N. J. 8 pages. Seeks to bring about "a matter-of-fact attitude" and use of "the correct vocabulary." The few reading references all include publisher's address and price. For free distribution only in New Jersey, but single copies will be sent free to health workers elsewhere. Request privilege of re-publication.

The Early Care of Children's Teeth, by Dr. L. J. Stephan. Milwaukee Health Dept. 12 pages. From birth to 6 years. *Free*.

Some day this writer hopes for careful consideration of how to select subject matter for those who most need health information. Should the early care of children's teeth be presented in two parts? How about using "Save The Baby Teeth!" for the mothers of babies?

List of Publications, National Committee for Mental Hygiene, 450 7th Ave., New York, N. Y.

Some of the advance papers of the International Congress on Mental Hygiene are available at 15 cents a copy. Ask for copy of list. Two of them: Educational Techniques for Mental Hygiene Societies, and Public Education in Mental Hygiene.

Publicity Material. American Society for the Control of Cancer, 25 West 43d St., New York, N. Y. *Free*. A list of available material.

Children's Bureau and Other Publications Relating to Children. Supt. of Documents, Washington, D. C. *Free*.

List of government publications for sale.

Foods and Cooking. Supt. of Documents, Washington, D. C. *Free*. List of government publications.

Living The Healthy Life, by Dr. J. F. Williams of Teachers College. John Hancock Mutual Life Ins. Co., Boston, Mass. *Free*. A "health manual" of 12 pages for those who will accept a manual touching upon a dozen aspects of healthy living.

Health Education Material. Dairy-men's League Coöperative Assn., 11 West 42d St., New York, N. Y. *Free*. Illustrated catalogue of publications and other material.

Publications and Policy of Distribution. Cleanliness Institute, 45 East 17th St., New York, N. Y. *Free*. Classified, descriptive list of publications and how to get them.

Among the Cleanliness Institute publications: The Great East Gate, by Dr. W. W. Peter, and Hitch-hikers, by Dr. Peter and G. T. Hallock. All health educators may and should have copies. When you have read or used either of them please tell me what you think of it. Hitch-hikers offers many ideas for exhibits and illustrated talks.

Eating for Efficiency. Evaporated Milk Assn., 203 North Wabash Ave., Chicago, Ill. 64 pages. Menus, recipes, calories and mineral values of common measures of food. *Free*.

Health Education and the School Lunch, and Why Evaporated Milk? illustrate use of rough finished paper, silhouettes as illustrations, and black with one color in printing. Address above. *Free*.

Citrus Fruit Recipes For Special Diets. California Fruit Growers Exchange, Los Angeles. *Free* for training classes.

MAGAZINE ARTICLES

"The Gland Route to Health," by Dr. G. F. Alsop. *Woman's Journal*, New York, N. Y. Dec., 1930.

"I Smell Smoke," by T. F. Dougherty. *Saturday Evening Post*. Jan. 31, 1931. Fire hazards and prevention.

"What Rights Has the Child?" by Dr. W. R. Ramsey. *Farmer's Wife*. Feb., 1931. St. Paul, Minn. *Free*.

"Our Ageing Population: Its Vital Effects," by Louis I. Dublin. *New York Times*. Jan. 4, 1931. Diagram.

CONVENTIONS

"Public Health Education—The Function of the University and of Private Foundations—The Functions and Limitations of Government in Public Health" will be discussed by the Health Division, National Conference of Social Work, Minneapolis, Minn., June 19, 1931.

The Educational Publicity Division, National Conference of Social Work, Minneapolis, Minn., will discuss: "Education of the Public on Mental Hygiene—The Public Mind on the Private Mind"; "Lessons in Public Relations from the Year 1930—Old and New Stereotypes"; "The Child and Propaganda—The Conundrum of the Educator—The Problem for Child Guidance"; "The Lessons From Difficult Causes"; "The Radio and Social Work—Does the Public Listen In?—Who is Broadcasting—and What?"

At Minneapolis in June the Social Work Publicity Council program will include: "Review of 1931 Publicity Awards"; "Round Table on the Newspaper in Social Work"; "Outstanding Publicity Ideas of the Year"; "What's On Your Mind: Questions and Answers on Publicity Practice"; "Round Table on Annual Reports and Annual Meetings."

"A School Health Program in Relation to Tuberculosis of Children," by D. J. Kelly, and "Public Relations," by G. A. Hastings, will be features of the National Tuberculosis Association convention, Syracuse, N. Y., in May.

An evening session of the Pennsyl-

vania Tuberculosis Society annual meeting was devoted to "Education for Health." One of the 3 addresses was by Dr. H. E. Kleinschmidt of the Public Health Education Section. Another feature was a joint luncheon session with the local Rotary Club.

The White House Conference will be discussed in an afternoon session of the annual meeting of the Iowa Public Health Assn.

Report of Magazine Coöperation With White House Conference. Mimeographed report showing an immense circulation of Conference material. Professional journals do not show up so well, due, doubtless, to the scarcity of real fact material about the Conference. Most of the news releases told of conditions and problems, while public health workers needed to know more about the plans for the studies and the Conference.

DATES AHEAD

May 1—Child Health Day—Emphasis upon "an adequate school health program adapted to meet the needs of each community," and the "support of adequate full-time community health service," are urged as May Day—Child Health Day—themes by the Conference of State and Provincial Health Authorities. Address: American Child Health Assn., 450 7th Ave., New York, N. Y.

May 10—Mother's Day—Address: Maternity Center Assn., 578 Madison Ave., New York, N. Y. "A Day to Save Mothers' Lives"; "to direct the attention of the American people to our deplorable maternal death rate—the highest in any civilized country." 8 electrotypes, in different sizes, for newspaper use supplied free. Also press copy, 400 up to 1,200 words, including: "The Waste In Mothers' Lives"; "They Never Knew Their Mothers"; "A Square Deal for Mothers"; "Stork Worship." Other forms of publicity suggested for state and local groups.

Departments and associations may "cash in" on the national promotion of the "Day" under the leadership of the well known Maternity Center Association.

May 12—National Hospital Day—Address: National Hospital Day Committee, 537 S. Dearborn St., Chicago, Ill. Some of "the larger radio and national advertisers have promised co-operation." This of course is a long established and successful event.

WHY DO THEY DO IT?

A memorandum of health activities in a city, located east or west of Montauk Point, is headed

A Review of New Activities initiated or accomplished at . . . during the past ten months.

But the memorandum is not dated! Nothing but a real letter is dated—according to the average stenographic mind. The way to avoid trouble in filing and sending out undated material is to have an office rule that *all material* going through a typewriter shall be dated *unless* contrary instructions are issued.

A 4-page T.A.T. folder of special merit is issued by "the Health Department" in some unnamed city. Why the modesty?

PLAYS

A play for adults: My Son John, by Drs. L. F. Wooley and D. K. Pratt. National Committee for Mental Hygiene, 450 7th Ave., New York, N. Y. 10 cents. "A mental hygiene playlet about a normal child." First presented at annual meeting of National Congress of Parents and Teachers.

The Treasure of Healthy Harbor. *Hygeia*, 535 North Dearborn St., Chicago, Ill. Feb., 1931. 25 cents. Another "pirate" health play for the 7th grade.

"Let's Give a Play," by O. Schrottky.

American Girl, 670 Lexington Ave., New York, N. Y. Feb., 1931. 20 cents. Makes much of simple settings and costumes—to make it easier to "give a play" about health—or for health's sake.

In the same issue of *American Girl*, the Girl Scout magazine, will be found "Plays to Act and Read," by S. L. Goldsmith, and "How About Marionettes?" The latter introduces the idea of home-made puppets.

DIPHTHERIA

"The Results of the 5-Year Toxin-Antitoxin Campaign" (now closed) in New York State. State Dept. of Health, Albany. Free.

The "Diphtheria issue" of *The Commonwealth* (Massachusetts Dept. of Public Health) included "A Diphtheria Immunization Campaign—Organization and Methods." July–Sept., 1930. Free.

Emphasis for the 24-sheet diphtheria prevention poster was gained in Lafayette High School, Buffalo, by an unveiling in the school auditorium. Illustrated in *S. C. A. A. News*, 105 East 22d St., New York, N. Y. Jan., 1931.

A progress report of the New York City campaign based on "the economic loss caused by diphtheria"—a press release. New York City Dept. of Health. Free. Can be worked over in other cities or states.

Two different blotters and a small handbill—Health Dept., Attleboro, Mass. No "hard words." Tell the 3 or 4 facts most necessary to get understood. Free.

A press release on diphtheria carriers—New York City Dept. of Health. Free. Also "Eight children's lives saved each week"—press release. Free.

The Berwyn, Ill., American Legion Post was awarded the State Adjutant's Cup—"for the outstanding piece of service among the children in Illinois"—for its local campaign for diphtheria immunization.

BOOKS AND REPORTS

USEFUL BOOKS OF THE PAST YEAR

MAZŮCK P. RAVENEL, M. D.

IN this review we have not confined ourselves entirely to 1930, since several exceptional books dated 1929 were published late in the year and notices of them did not appear until 1930. Further, we omitted our 1929 annual review. We have limited ourselves almost entirely to books which will be of use to the public health worker in the many fields embraced under that title.

The classification has been somewhat difficult and under "miscellaneous," especially, will be found a number of works which might well be placed elsewhere. Works on bacteriology which include immunity, as practically all of them do, have been included under bacteriology.

While we have depended chiefly on reviews in our own columns, we have also consulted a number of leading American and English journals. Practically all the English publishers have agencies in America, some of which put out the books under their own names, so that they may be obtained as easily as those published here.

On bacteriology, we have three works of unusual value. The Medical Research Council of England is publishing *A System of Bacteriology in Relation to Medicine*, written by many authors, and published by His Majesty's Stationery Office. Several volumes have appeared during the year. For succinctness and accuracy of statement, as well as practical value, this is easily the most valuable work on this subject in the English language. Of equal value, as far as it goes, is *The Principles of Bacteriology and Immunity*, by Topley and Wilson,

William Wood. An excellent book on a subject too little known is *Molds, Yeasts and Actinomyces*, by A. T. Henrici, Wiley. The Pickett-Thompson Research Laboratories have issued Volumes V and VI on the *Pathogenic Streptococci*. Volumes II and III of *Physiology and Biochemistry of Bacteria*, by R. E. Buchanan and Ellis I. Fulmer, Williams and Wilkins, are important and of great interest. Very useful books are *A Compilation of Culture Media for the Cultivation of Microorganisms*, by Max Levine and H. W. Schoenlein, Williams and Wilkins, and *Bacterial Metabolism*, by Marjory Stephenson, Longmans, Green & Co. *The Bacteriophage and Its Clinical Application*, by F. D. d'Herelle, Charles C. Thomas, treats of a much discussed phenomenon. *An Introduction to Malarology*, by Mark F. Boyd, a master of the subject, Harvard University Press, is worthy of especial praise from every standpoint, and *The Geographical Distribution of the Malaria Carrying Mosquitoes*, by H. W. Kumm, *American Journal of Hygiene*, goes with it appropriately.

Immunology has, as usual, held the interest of laboratory workers as well as clinical men. The following can be recommended: *The Chemical Aspects of Immunology*, by H. Gideon Wells, Chemical Catalogue Company; *The Immunology of Parasitic Infections*, by William H. Taliaferro, Century Company; and *Immunity in Infectious Diseases*, by Besredka, Williams and Wilkins.

The laboratory worker will welcome

the third edition of *Laboratory Methods of the United States Army*, by Charles F. Craig, Lea & Febiger; and the 7th edition of *Lehmann's Medical Hand Atlases—Determinative Bacteriology*, Volume I, Translated by R. S. Breed, G. E. Stechert. *Laboratory Medicine*, by Daniel Nicholson, Lea & Febiger, is an excellent work, and though designed chiefly for clinical medicine, contains much of value to the public health worker. *The Report of Second Conference on the Sero-Diagnosis of Syphilis*, World Peace Foundation, is also of great practical importance.

Two outstanding books on water supply and sewage disposal have appeared: *Water Supply Engineering*, by Babbitt and Doland, McGraw-Hill; and *Sewerage and Sewage Disposal*, by Metcalf and Eddy, McGraw-Hill.

The output on personal, industrial, mental, sex and general hygiene has been large. Under this general heading we have included some books which might well have been placed elsewhere, because while their titles do not indicate that they are particularly devoted to hygiene, the authors have given much attention to prevention. The following have been selected as typical in their respective lines: *The Diagnosis of Health*, by William R. P. Emerson, Appleton; *The Hygiene of the School Child*, by Terman and Almack, Houghton Mifflin; *Hygiene for Nurses*, by Guy and Linklater, Wood; *Outline of Preventive Medicine*, Edited for New York Academy of Medicine, by Sondern, Heyd and Corwin, Hoeber; *A Textbook of Hygiene*, by J. R. Currie, Wood; *Military Preventive Medicine*, by George C. Dunham, *Army Medical Bulletin No. 23*; *Personal Hygiene for Nurses*, by Seneca Egbert, Davis; *The Principles and Practice of Hygiene*, by Smiley, Gould and Melby, Macmillan; *Artificial Sunlight—Combining Radia-*

tion for Health with Light for Vision, by M. Luckiesh, Van Nostrand; *Tuberculosis Among Children*, by J. A. Myers, Thomas; *Personal and Community Hygiene*, by C. E. Turner, Mosby.

Under industrial hygiene we have *Psychology and Industrial Efficiency*, by Harold Ernest Burtt, Appleton; *Incapacity or Disablement in Its Medical Aspects*, by E. M. Brockbank, H. K. Lewis; *Trauma, Disease Compensation—A Handbook of their Medico-Legal Relations*, by A. J. Fraser, F. A. Davis; *Is It Safe to Work? A Study of Industrial Accidents*, by Edison L. Bowers, Houghton Mifflin; and *The Human Factor in Industry*, by E. P. Cathcart, Oxford University Press. A new departure, useful to the laboratory man as well as the specialist in industrial hygiene, is *Industrial Microbiology*, by Smyth and Obold, Williams and Wilkins. There has been a great development in this subject since the World War, much of the material still being found only in technical journals.

Writers on sex hygiene have given us *Factors in the Sex Life of Twenty-two Hundred Women*, by Katherine Bement Davis, Harper; and *Sterilization for Human Betterment*, by Gosney & Popenoe, Macmillan.

On mental hygiene we cannot but single out *Introduction to Mental Hygiene*, by Groves and Blanchard, Henry Holt. This is a subject too little understood by the general physician and many books concerning it are written in language difficult for the average person to understand. This particular work has not only been very highly praised by specialists, but is written in language which makes all of its teachings available to the average reader. Other excellent books on this subject are: *Practical Psychology and Psychiatry*, 6th edition, by C. B. Burr, Davis; *Social Control of the Mentally Deficient*,

by Stanley P. Davies, Crowell; *The Adolescent: His Conflicts and Escapes*, by Schwab & Veeder, Appleton; and *Mental Deficiency*, 5th edition, by A. F. Fredgold, Wood.

In spite of the attention which oral hygiene has attracted for several years, as evidenced by the work in England, and the studies in America, some of which are under the Foundations, few books have appeared on the subject. We can recommend *Mouth Infections and Their Relation to Systemic Diseases*, by Malcolm Graeme MacNevin and Harold Stearns Vaughan, issued by the Joseph Purcell Research Memorial. From England we have a most valuable report, *Special Report Series, No. 140, Diet and the Teeth: An Experimental Study, Part I*, by May Mellanby; His Majesty's Stationery Office, published in November, 1929.

The social and economic status has much influence on health. We can recommend *The Social Worker in Family, Medical and Psychiatric Social Work*, by Louise C. Odencrantz, Harper.

The study of children from every standpoint has received an impetus through the studies made by the various committees of the White House Conference. Most of this material is not yet in book form and cannot be offered for some time to come. Two books have been recommended by the reviewers: *Creative Activities in Physical Education*, by Olive K. Horrigan, A. S. Barnes; and *Baby's First Two Years*, by Richard M. Smith, Houghton Mifflin.

Epidemiology is represented by the following: *Epidemic Encephalitis—Report of Survey by Matheson Commission*, Columbia University Press; *Undulant Fever and Contagious Abortion*, by L. C. Bulmer, Technical Service Bureau; *Diseases Transmitted from Animals to Man*, by Thomas G. Hull, Charles C. Thomas; and *The Epidemiology and Control of Malaria in Palestine*, by I. J.

Kligler, Chicago University Press. The work on encephalitis does not arrive at any conclusions because the disease offers many problems which are as yet unsolved, but we know of nothing which contains anything like the amount of information on the subject that this report gives.

Two unusually good books on tuberculosis, especially the relation of the disease in animals to human beings, deserve attention: *Tuberculosis in Man and Lower Animals*, by H. H. Scott, His Majesty's Stationery Office; and *The Prevention of Human Tuberculosis of Bovine Origin*, by William G. Savage, Macmillan.

There have been a number of short books on various aspects of food and feeding from which we have selected: *Feeding the Family*, 3d edition, by Mary Schwartz Rose, Macmillan; *Deficiency Diseases, Including Osteomalacia and Tetany*, by Alfred F. Hess, Lea & Febiger; *The Most Nearly Perfect Food: The Story of Milk*, by Crumbine and Tobey, Williams and Wilkins; and *Grow Thin on Good Food*, by Luella E. AxteLL, Funk & Wagnalls.

Parasitology is well represented by: *A Manual of External Parasites*, by H. E. Ewing, Charles C. Thomas; *Hookworm Disease, Its Distribution, Biology, Epidemiology, Pathology, Diagnosis and Control*, by Asa C. Chandler, Macmillan; *Insects, Ticks, Mites and Venomous Animals of Medical and Veterinary Importance*, by Patton and Evans, H. R. Grubb, Ltd.; *Introduction to Human Parasitology*, 4th edition, by Asa C. Chandler, Wiley (replacing *Animal Parasites and Human Diseases*); and *Handbook of the Mosquitoes of North America*, by Robert Matheson, Charles C. Thomas.

Tropical Medicine is represented by: *Tropical Medicine*, by Rogers and Megaw, Blakiston, based on the extensive experience of the two well known

men in the tropics and original in arrangement and treatment; and *Tropical Medicine in the United States*, by Alfred C. Reed, Lippincott.

Several excellent biographies and autobiographies have appeared of which the following are of especial value: *Medical Leaders from Hippocrates to Osler*, by Lambert and Goodwin, Bobbs-Merrill; *Harvey W. Wiley*, Bobbs-Merrill; *Edward Jenner and the Discovery of Smallpox Vaccination*, by Louis H. Roddis, published by the author; and *Health Heroes. Edward Livingston Trudeau*, by Hallock & Turner, Heath. The most notable biography in many ways is *The Book of My Life*, by Jerome Cardan, translated from the Latin by Jean Stoner, E. P. Dutton. Cardan was a remarkable character from many standpoints, the leading physician of his time as well as a great mathematician. His character was full of apparent contradictions, and his story has now for the first time been made available to the average reader. *Plarr's Lives of the Fellows of the Royal College of Surgeons of England*, by Sir D'Arcy Power, John Wright & Sons, gives the histories of many famous discoverers of medical facts.

Many books must be classed under "Miscellaneous," some of these written for the public in nontechnical language, but containing material which the average health worker and physician will appreciate. Some of the outstanding are: *Health—What Everyone Ought to Know*, by Oliver T. Osborne, Thomas; *Disease and the Man*, by George Draper, Macmillan; *The Art of Rapid Reading*, by W. B. Pitkin, McGraw-Hill; *The Story of San Michele*, by Axel Munthe, Dutton; *The Biological Basis of Human Nature*, by Jennings, W. E. Norton; *Getting Well and Staying Well—A Book for Tuberculous Patients, Public Health Nurses and Doctors*, by John Potts, Mosby; *Science in the Service of*

Health, by Elliot R. Downing, Longmans, Green and Co.; *Pioneers of Public Health—The Story of Some Benefactors of the Human Race*, by M. E. M. Walker, Oliver & Boyd; *Practical Medical Dictionary*, 11th edition, by Thomas Lathrop Stedman, Wood; *The Development of Physiological Chemistry in the United States*, by Russell H. Chittenden, The Chemical Catalogue Company; *Dietetics in Warm Climates*, by J. Neil Leitch, Robinson & Sons; *Allergic Diseases*, by Ray M. Balyeat, Davis; *Seventy Birth Control Clinics*, by Caroline Hadley Robinson, Williams & Wilkins; *Civilization and The Cripple*, by Frederick Watson, John Bale, Sons & Danielson; *History of Haitian Medicine*, by Robert P. Parsons, Hoeber; *Human Biology and Racial Welfare*, by E. V. Cowdry, Hoeber; *Medicine, Its Contribution to Civilization*, by E. B. Vedder, Williams & Wilkins; and *Recent Advances in Preventive Medicine*, by J. G. C. Haslam, Blakiston. *The Money Value of a Man*, by Louis I. Dublin, Ronald Press, shows the useless loss of wealth by premature deaths. Without wishing to appear partial we cannot but call especial attention to *The Story of San Michele*, which is largely an autobiography, as one of the most remarkable books which has been published during the year. Its popularity and human interest is attested by the fact that 30 reprints were printed in 12 months.

On the legal side, we note *A Survey of the Law Concerning Dead Human Bodies*, by G. H. Weinman, National Academy of Science, which is of interest to many classes of readers; and *The Doctor in Court*, by Edward Huntington Williams, Williams & Wilkins.

At a time when athletics is being so widely discussed, the *Symposium on Physical Education and Health*, edited by Jay B. Nash, New York University Press, will be found most useful. An-

other good book is *Handbook of Physical Education*, by E. G. Schroeder, Doubleday, Doran.

Lastly, *Blood Grouping in Relation to Clinical and Legal Medicine*, by L. H. Snyder, Williams & Wilkins, calls for attention. Written largely from the biological standpoint, it contains facts of general and practical interest.

Medical Biometry and Statistics—

By Raymond Pearl. (2d ed rev.) Philadelphia: Saunders, 1930. 459 pp. Price, \$5.50.

The word "statistics" seems destined for a place in the lists of words of greatest usage which lexicographers compile in their idle moments. The world has long known the power of the printed word; now it may come to recognize the even greater effect of a statistical formula.

When, in 1923, Raymond Pearl published his *Introduction to Medical Biometry and Statistics* he made available to public health workers all the well tested procedures which a medical statistician is ever likely to employ. Now we have the second, completely revised and enlarged edition of this valuable work. Pearl has wisely omitted certain topics of purely theoretical interest, such as his Classification of the Causes of Death for Research Purposes. He has added much useful material dealing with the preparation of record forms and their tabulation, a new chapter on the logistic curve, and, as part of Chapter I, a new section on the Nature of Statistical Knowledge. This section will repay the most attentive reading even by a trained statistician.

There is great temptation to quote from it freely, but space will permit of but one sentence: "Very likely some will not agree with its reasoning or its tentative conclusions, but even in such event, it may help the disagreeing reader to the more complete ordering of

his own ideas about statistical concepts."

This observation illustrates what the reviewer considers as Pearl's greatest contribution to the field of biometry. His work has frequently called forth the expression (at times, violent) of opposing views. The important point is that were it not for his prolific researches it probably would not have occurred to many of his opponents to investigate the disputed subjects at all.

The book is thorough and exact in statements of fact, stimulating and open-minded in interpretation. The changes in the new edition have made an excellent book even more meritorious.

J. V. DEPORTE

The State Departments of Massachusetts, Michigan, and Ohio—*By James Wallace, M.D. (Sponsored by the Committee on Administrative Practice, American Public Health Association.) New York: Commonwealth Fund Division of Publications, 1930. 192 pp. Price, \$1.50.*

Dr. Wallace has made a detailed study of the state health organization of 3 states having an approximately equal population. These states were well selected, in that each represents a somewhat different type of population, having varying governmental procedures and traditions. Each state has an active health service, with wide divergence of viewpoint in relation to general policies.

The book begins with a short chapter on the origin and present form of the 3 state health departments. Local health organization in each state is considered briefly, and there is a short chapter on appropriations and expenditures. The author has not considered each state separately, but has divided the book in accordance with the functions of a state health organization and has summarized the activities of all in relation to each separate function.

For example, tuberculosis control (p. 81) is treated in a short chapter. The activities of each of the states in relation to tuberculosis control are outlined. The author makes no comparisons, but the material is suitably compiled, so that the reader can make his own.

In the final chapter, the author gives a brief critical statement in regard to the organization, activities, and policies of the states under consideration.

The appendix gives the *Appraisal Forms* for rural and municipal health service as adopted by the American Public Health Association. These forms are inserted "for those who may wish to measure the achievement of the three state health departments." Since these *Appraisal Forms* relate to local health organization they have little utility as a means for measurement of achievement of state health work.

Students of state public health administration will secure much information from a careful study of Dr. Wallace's book. WILSON G. SMILLIE

Study Guide Test-Book in Hygiene
—By Dean Franklin Smiley, Adrian Gordon Gould, and Elizabeth Melby.
New York: Macmillan, 1930. 70 pp.
Price, \$.80.

This test-book is designed as an aid in the preparation of lesson assignments based on *The Principles and Practice of Hygiene*, designed largely for nurse training. There are 26 sections or sets of lesson questions arranged in such a way as to cover 30 class hours.

The test content is made up of various types, some of which are ordinary questions requiring a written answer, others problems of which the following is a sample:

The following situations have been reported:

a. A 10-year-old child is living in the same home with a 6-year-old brother who has tuberculosis of the knee.

b. A child was born of a mother with ad-

vanced pulmonary tuberculosis but was at once placed in the home of a healthy relative.

c. A 14-month-old child is with its mother who is an active uninstructed case of pulmonary tuberculosis.

d. An 8-year-old child is living in the same home with its father who 10 years before returned from a modern tuberculosis hospital as an arrested case of pulmonary tuberculosis and has had no symptoms since.

List these situations (by their corresponding letters) in the order of their importance to the exposed child:

1.....2.....3.... 4.....

There are also questions of a type similar to the "True and False" but containing a sufficient number of statements regarding a given case so that they are a real test of information.

While at first glance such a scheme seems somewhat mechanical, it does cover the ground in a thorough way and has distinct advantages as a guide to the teacher of the class in hygiene. One objection would be, of course, that after it has been used a year or two, the lazy student will get the proper answers from some one who has previously taken the course. On the whole, this is a desirable addition to the technic of teaching hygiene. CHARLES H. KEENE

Seventy Birth Control Clinics. A Comprehensive Survey and Analysis which Includes the General Effects of Control on Size and Quality of Population. The Nature, Extent and Status of a World-wide Movement Objectively Presented. First of a Series of Monographs on the Medical Aspects of Human Fertility Published under the Auspices of The National Committee on Maternal Health—By Caroline Hadley Robinson. Baltimore: Williams & Wilkins, 1930. 351 pp. Price, \$4.00.

The title and subtitle of this book describe it as well as any review can. It is a piece of work which has been conscientiously done, with the advice of

notable men and women, and can be regarded as an authoritative exposition of the subject as it now stands.

Chapter X which treats of the benefits which may be expected will probably strike the average reader as being too optimistic. If these could be reasonably assured, those who believe in birth control would have enormous accession to their ranks.

The book is well printed, well documented and has a good index. There are several useful appendixes.

M. P. RAVENEL

Grow Thin on Good Food—By Lucilla E. Axtell, M.D. New York: Funk & Wagnalls, 1930. 336 pp. Price, \$2.00.

The problem of reducing is largely one of will power and practical knowledge of the nutritive values of food and the essential needs of the body. The author makes her reader face the situation at the outset: "You cannot run away from a weakness; you must sometime fight it out or perish." But she also holds up visions of the gains to the victor—improved health, better looks, and freedom from the "humiliation, dejection and shame of being fat." Excellent advice is given in a very simple, entertaining fashion, always with the plea for intelligent mastery. "Anyone, no matter how stupid, can follow an 'Eat this' system but to look into the subject intelligently requires brains, brains and character."

About two-thirds of the book is devoted to proper food and one-third to proper exercise. There is very practical advice about the selection of food, for instance choosing meat as free from fat as possible, making veal the staple meat because of its leanness, cooking it occasionally in the water from boiled ham for "near ham."

There are recipes which use attractive ways such non-fattening aids as

washed bran, India gum, agar-agar, mineral oil, and saccharine. A program of pleasing and original meals for a month, including measures and recipes, provides for a woman 5 feet 4 to 4½ inches tall, with modifications for others of greater height. Programs with plainer foods, programs for men, and for those who must eat what is served, indicate the careful efforts of the author to meet varying needs.

Instruction regarding exercise is also sane and practical, emphasizing the importance of regularity and the value of play rather than drudgery.

There are some inaccuracies, such as the statement that adults need little vitamin A, and that whole wheat, peas and beans may be regarded as sources of this very important factor. Some provision of cod liver oil or one of its concentrates to insure a high vitamin A intake would seem desirable. It is regrettable that lean meat should be recommended as a source of vitamins, when it is of almost negligible value save for vitamin G, while liver, with its high vitamin content, is given no emphasis. The substitution of the common yeast extracts rich in vitamin B for bouillon cubes with practically no nutritive value would be in line with the author's aim to keep the supply of vitamins high. On the whole the book is a most welcome popular interpretation of the way in which reducing may be accomplished on truly good food, attractive in form and flavor as well as a means to health, beauty, and happiness.

MARY S. ROSE

Safety Town Stories—By Mildred Miles Roberts. Chicago: Lyons & Carnahan. Price, \$.60.

In this story book for boys and girls, ages not stated, Sally Safe is a girl who always does the careful thing, looks before she leaps, washes her hands before she eats, gives penny lectures to her

sister Susie Sorry, who, as you may have guessed, always does the wrong thing and reaps the inevitable consequences of her carelessness. To the adult mind, the stories are simply appalling, but undoubtedly to the child they are as natural and as absorbing as the so-called funnies are delightful.

Who can tell whether reading these stories will cause children to be more cautious, to abstain from dangerous pastimes? Is caution an entirely desirable trait? Probably only good results from the reading, but it is possible that the more sportingly inclined youngster might try to do Susie Sorry one better just to see what would happen.

Health workers with a flair for child behavior might put the book to the test. It is attractively printed and illustrated, and ought to be most acceptable to children.

RAYMOND S. PATTERSON

Strategy in Handling People—By *Ewing R. Webb and John J. B. Morgan*. Chicago: Boulton, Pierce, 1930. 260 pp. Price, \$3.00.

The question may well be asked why this book should be noticed in these columns. It is not a public health book, and moreover it can hardly be designated as scientific; yet it contains a vast amount of practical information directly applicable to the daily task of the health executive.

Many a health officer has discovered to his surprise that his success in inaugurating and developing an effective health program depends less on his technical knowledge and scientific training, which he has perhaps systematically labored for years to acquire, than on ability to get appropriating bodies and influential individuals to give him the necessary practical support. This ability which is generally assumed to be an intuitive trait of personality or acquired without special study is here revealed to be susceptible of development by the process of learning.

It is a textbook on successful human relationships. There is little that is new in it and the scientific principles of psychology have been indicated in only the slightest degree to substantiate its empirical presentation. The authors have, however, rendered a valuable service in classifying some 20 or more types of ordinary business, diplomatic and political relationships and illustrating by concrete examples how they have been successfully handled by eminent persons. The conversational style in which the incidents are elaborated makes the book easily readable.

It is remarkable to note in a book on this subject that among the hundreds of illustrious personages used as examples, the only woman is Evangeline Booth. Over three hundred references are given, most of which are to biographies.

A careful study of this book by public health workers and the skillful application of its principles with the right people should increase public health facilities far beyond those which have been attained by preachment, persuasion, publicity and politics. No indication is given as to what will happen when everybody has learned the lessons given and we all "strategically" handle each other.

HOMER N. CALVER

A Manual of the Common Contagious Diseases—By *Philip Moen Stimson, M.D.* Philadelphia: Lea & Febiger, 1931. 351 pp. Price, \$3.75.

This manual is the outgrowth of notes on lectures given at the Cornell University Medical College. It is intended primarily as a clinical guide for medical students and internes, though the author expresses the hope that it will be found useful for nurses and practitioners of medicine, especially those engaged in school work.

It is well written, up-to-date, and gives all of the facts concerning etiology, symptoms, treatment, prevention, and the protection of contacts, which is re-

quired. There is a glossary which should not be needed for those capable of understanding the text, and a useful table giving a summary of the most common contagious diseases.

The chapter on General Management of Contagious Diseases, which includes the technic and rules practised at the Willard Parker Hospital, with which the author is connected, is most useful. The illustrations are excellent.

It strikes us as being one of the best of its type which has come to our attention. It can be unhesitatingly recommended. The printing and make-up are excellent.

M. P. RAVENEL

Tests and Measurements in Physical Education—By *John F. Bovard and Frederick W. Cozens*. Philadelphia: Saunders, 1930. 364 pp. Price, \$2.75.

This is an outstanding contribution to the scientific side of physical education. It discusses the need and use of physical tests; gives a historical sketch concerning the development of measurements in physical education; and discusses in considerable detail the typical contributions in the field, covering such factors as anthropometric measurements, strength tests, cardiac functional tests, ability and adjustment tests for elementary and secondary schools, and for colleges for both men and women. It includes also tests on neuromuscular control, and those using sport technic as a measuring rod.

There is an excellent section on tools of measurement covering such factors as elementary statistical methods, graphical methods, and methods of scoring tests. There is a third section on the theory and practice of test administration.

An excellent bibliography in the field of physical tests and measurements, and an appendix made up largely of tables necessary for scoring certain outstanding tests end the book.

While this book is an expansion and a rearrangement of a University of Oregon publication by the same authors issued in 1926, it is much more complete, and much better arranged.

This excellent contribution does for physical education what so many other authors have endeavored to do for other types of education.

CHARLES H. KEENE

Ethics Talks to Nurses—By *Mary E. Gladwin*. Philadelphia: Saunders, 1930. 281 pp. Price, \$2.00.

The more one deals with nurses the more he is impressed with the important part good nursing ethics plays in their professional success. And since ethics means the science of duty or of conduct from the standpoint of right or wrong it is absolutely fundamental.

The author displays rare common sense and a fine insight into psychological principles. For instance, sentences like these ring true: "Nervousness is often a form of selfishness," and "A good deal is said about the necessity for *self sacrifice* on the part of nurses when what is really meant is *self control*."

Every point made in the book is well illustrated by a concrete example which is obviously drawn from long experience in nursing practice and nursing teaching. The chapter on "The Patient and the Nurse" is especially good. Miss Gladwin shows here that many nurses show no lack of skill or technical knowledge yet they fall short of being true nurses by displaying little mannerisms and habits which might be put under the heading of bad manners. She shows that the first duty of the nurse is to study and know herself and subject herself to rigorous self discipline so that she may have the poise and delicacy of touch and feeling which contribute to the art of nursing.

Some of the chapter titles are Observation, Gossip, Truth, Discipline,

Punctiliousness, The Opposite Sex, Good Manners, Fees and Gifts, Vocabularies and Books, and Success. The last chapter, entitled *Our Exemplar*, constitutes a rare climax; it is really the most unique and beautiful thing about the book, for *Our Exemplar* is none other than Florence Nightingale herself. One has only to read of her life and character to know that she epitomized all our ideals of nursing ethics.

Miss Gladwin's little book deserves to be widely used not only in nursing schools but among graduate nurses, who will emerge not only better nurses but better women after spending an hour or two immersed in its pages.

EVA F. MACDOUGALL

Laboratory Medicine. A Guide for Students and Practitioners—*By Daniel Nicholson, M.D. Philadelphia: Lea & Febiger, 1930. Price, \$6.00.*

This is justly called a guide for students and practitioners. It does not contain all the various tests found in some of the older and more voluminous texts, but gives briefly and clearly the various laboratory procedures of proven value in the diagnosis of disease. It shows a real effort to explain the rationale of and indications for the various diagnostic procedures described, this being one of the most valuable features of the book, especially to the student.

There are included some of the newest diagnostic tests which heretofore have been found in various journals, as the biological test for pregnancy of Ascheim and Zondek, newer methods for investigation of the gastric secretion by the hypodermic injection of histamine, and the use of blood grouping in cases of disputed parentage. Other important sections are found on classification of anemias; recent views on hematology; classification of nephritis with the typical urinary findings in each

type; use of convalescent serum in treatment of measles and poliomyelitis; cutaneous reactions to proteins; and rapid microscopic tissue examination of Terry.

Some omissions are noted, as the recent work of Sabin on the rapid method of typing pneumococci, the value and utility of which is well established, the examination of skin lesions for blastomycetes and sporothrices, the Kahn tests for brucellosis and tularemia. The test for non-protein nitrogen is not given, since the blood urea nitrogen has the same significance. The wisdom of including therapeutic hints in a volume of this sort is probably open to question in principle.

We hope that these minor defects will be remedied in a second edition. In the meantime it can be said that this is one of the best of books on its subject. The printing, illustrations and make-up are excellent.

LOUIS F. HOWE

Annals of the Pickett-Thomson Research Laboratory. The Pathogenic Streptococci. Vol. 6. The Role of the Streptococci in Scarlet Fever—*By David Thomson and Robert Thomson. Baltimore: Williams & Wilkins, 1930. 470 pp., 13 pl. Price, \$10.00.*

A careful survey of the vast literature on scarlet fever is presented in this volume of the series on the streptococci. Fortunately the authors have devoted the entire volume to scarlet fever, reviewing published work in some 1,400 papers. Due to the discovery of the Dick toxin and the Dick test, researches during the past 5 years have been greatly stimulated and this entire field is here carefully presented. (For a full account of the various researches on the etiology of scarlet fever up to the year 1924 the reader is referred to Volume I, pages 115 to 172 of this same series.)

The bacteriology, immune reactions, diagnosis, infectivity, modes of trans-

ference, and complications of scarlet fever, as well as such problems as are presented, for example, by carriers, are presented in a manner which is clear and unbiased and will permit the reader to form his own conclusions. An example of the variety is found in studies on the spread of scarlet fever by books. It has been found that, under experimental conditions, *Streptococcus scarlatinae* will survive on inoculated books and can be recovered from them during a period of 4 weeks.

Probably the most immediately helpful part of the monograph, apart from the preface, is the authors' summary and conclusions. Fifteen points are presented which appear as different lines of proof that scarlet fever is caused by a specific hemolytic streptococcus, called the *Streptococcus scarlatinae*. By means of sugar tests, litmus milk test, and the iodine test *S. scarlatinae*, *S. erysipelatis*, *S. puerperalis*, and *S. pyogenes* can be differentiated.

This monograph is a tribute to careful editing and printing. Excellent plates of photographs and a careful index add to this distinctly valuable contribution to our literature on the streptococci. ESTHER W. STEARN

The Guidance of Mental Growth in Infant and Child—By Arnold Gesell. New York: Macmillan, 1930. 317 pp. Price, \$2.25.

Dr. Gesell, in this new volume, has brought together, in a number of brief chapters, many phases in the growth and development of the child. The historical backgrounds are delightfully sketched so that one may follow step by step the ideas and methods adopted in our guidance of the child. The most unique chapter is entirely pictorial, being made up of reproductions of fascinating engravings by Currier and Ives, illustrating child life in the early 19th century. It gives one a sense of the great distance we have travelled in child

welfare since the Victorian era. The latter part of this same chapter sets forth a series of photographs relating to child development and child guidance, taken in the observatory playground of the Yale Psycho-Clinic. Here one may study the child as he really is, untrammelled by adult modes.

The chapters on the history of the kindergarten in relation to its new rôle, and the growth of the nursery school movement point out the differences in the English and American organizations, and give an excellent evaluation of their functions. Part II presents problems and methods of child guidance, illustrated by the results of Dr. Gesell's measurements of observations of the mental growth of the child, which bear out his thesis that differences in mental reactions may be studied and measured early in the first year and that these differences project themselves into the later years. The chapter on accidental deaths of young children is timely and practical.

Part III gives an excellent brief sketch of the science and protection of child growth in which the relation of heredity to mental growth is concretely set forth.

Perhaps the most signal value of this book is the orientation it gives to the whole subject and the stimulus to further research. It is thought provoking. Dr. Gesell, always the investigator and inspiring teacher, reveals his many-sided interests here. R. A. BOLT

A System of Bacteriology in Relation to Medicine. Vol. VII. Virus Diseases, and Bacteriophage—The Medical Research Council. London: His Majesty's Stationery Office (Distributed in the United States by The British Library of Information, French Bldg., 551 Fifth Ave., New York), 1930. 509 pp. Price, \$6.00.

The Introductory Survey (Chapter I), written by W. E. Gye and J. C. G.

Ledingham, presents problems as to the nature of viruses. Their study shows them to possess few peculiarities other than dimensional, which mark them off unequivocally from visible microbes, though the inclusion bodies in cells noticed in a number of virus diseases should be emphasized, because so far it has not been possible to produce similar structures by means other than the particular virus.

Recent investigations by Hadley, and other American workers, on the filtrable stages of well known organisms suggest that the final word as to the distinguishing differences between viruses and bacteria has not been written.

The difficulties encountered in culturing viruses in the absence of living tissue closely parallel those met in the slow and gradual growth of the filtrates of certain ontogenetic forms of bacteria, though for the latter the presence of living tissue is not a requirement. The authors of this chapter feel that the onus of proof rests on those who suggest that viruses are not living entities but ferments or enzymes. The known facts supporting the various ideas as to the nature of viruses are briefly discussed.

Chapter II, on cell inclusions, is concluded with instructive suggestions as to methods whereby our present unsatisfactory knowledge may possibly be improved by "illuminating facts."

The greater portion of the book is devoted to a consideration of specific virus diseases of plants and animals, particularly the latter. Chapters are written by various authors and there is considerable diversity in the method of presentation. Thirty-six pages are devoted to bacteriophage and cognate phenomena.

To each chapter references are appended. It is to be regretted that an index is missing, for a table of contents may serve a student while at school, but an index is requisite for the ready ref-

erence demands of those in advanced and research work.

Volume VII of the *System of Bacteriology*, written under the auspices of the Medical Research Council of England, may be rightfully considered as particularly stimulating to research. Few problems in medicine are more provocative of thought and subsequent research than are those relating to the virus diseases and the bacteriophage. There has never been so urgent a call for complete coöperation of the many branches of biological and physical sciences in bacteriological research as in the present epoch making but chaotic time. These volumes are welcomed for their clear presentation of at least a large part of the knowledge of medical bacteriology, much of which is in the experimental stage.

ESTHER W. STEARN

The History of Physical Education in Colleges for Women—By Dorothy S. Ainsworth. New York: Barnes, 1930. 116 pp. Price, \$2.00.

This is a very much worthwhile effort to trace the development of physical education in 12 of the oldest colleges for women, with a brief introductory chapter sketching the development of physical education in the United States.

The chapters cover such problems as the development of the theory of physical education for women; the growth of the programs; the gradual installation of equipment; the number and types of activities of the staffs; the departmental organization used; the organization and activities of athletic associations; and the gradual modification of costume up to the present one permitting freedom of movement.

Summarized, the author concludes that the most outstanding responsibilities of the physical education department are: (1) to ascertain the physical condition of each student; (2) to pre-

sent a program which will meet the need of each student, taking into consideration her differences of individuality, skill, and vitality; (3) to give the student sufficient skill and interest in some activity to make probable the continuance of this activity both in and after college; (4) to offer the student situations in which she may express and develop her own ideas; (5) to have a program which in the eyes of the majority of the students is reasonable and interesting; and (6) to stress consistently definite standards of conduct.

Thoroughly trained teachers with high ideals are essential to the success of such a program.

CHARLES H. KEENE

Ergebnisse der gesamten Tuberkuloseforschung—Herausgegeben von H. Assmann, Leipzig; H. Beitzke, Graz; H. Braeuning, Hohenkrug-Stettin; St. Engel, Dortmund. Vol. 2 (Leipzig, Georg Thieme), 1931. 490 pp., 106 figs. Price, M. 45 bound.

The second volume of this monograph by specialists on the various phases of tuberculosis has 10 sections dealing mainly with the disease, its acquisition, pathology, detection, and treatment. The opening chapter by Dr. Blumenberg of Berlin is, however, devoted to the much contested question as to whether or not there is an invisible or filterable form of the tubercle bacillus. He concludes that overwhelming proof of the existence of an ultra-visible TB-form is still lacking, though evidence for its polymorphism is incontestable.

The pathological anatomy of apical tuberculosis of the lungs is described and figured by Drs. Loeschke and Dehoff. An interesting review and discussion of extra-domiciliary infection is given by Dr. Ickert, who notes that the earlier categories of classification of the sources of infection are, in the light of current

knowledge, no longer adequate, and, moreover, that statistical data as usually obtained have less critical value than single fully investigated cases. Factors such as the hereditary disposition or constitution, and the extent, rate, and sequence of infections, enter into and complicate the problem of separating the domiciliary from the extra-domiciliary origin of tuberculosis.

Studies made by Ickert in East Prussia on 994 infected children show the highest percentage of infections (19.7 per cent) to have had their origin from tuberculous teachers. Next in order (17.3 per cent) were infected school children, (15.1 per cent) members of the family, (9.5 per cent) children of families in which active tuberculosis was present, (8.8 per cent) unknown, (8.1 per cent) other members of the household, (4.9 per cent) business and professional contacts, (4.2 per cent) visiting relatives, (4.2 per cent) visiting children from tuberculous families, and (only 0.4 per cent) from tuberculous cows.

Other chapters deal with sanatoriums for the tuberculous, selection of patients for treatment, clinical concepts of tuberculosis in the light of the French investigations, mineral metabolism and water turnover in tuberculosis, artificial bilateral pneumothorax, prognosis in tuberculosis in children, and the anatomy, radiology, and clinical significance of interlobar clefts.

The book has full bibliographies and an author and subject index.

C. A. KOFROID

Problems in Contemporary County Government—By Wylie Kilpatrick, Institute for Research in the Social Sciences, University, Virginia, 1930. 666 pp.

A comprehensive survey of the process of county administration in the State of Virginia is presented in this volume.

Each of 7 main divisions is devoted to an essential aspect of county government, including functions, finance, area, personnel, physical plant, relationship, and management.

Under the coöperative health units are outlined: (1) the definition of the county health board and accompanying organization, (2) the division of responsibility between the state and county, (3) the staff attached to the county health agency. The county health agencies include in their functions such vital factors as the registration of vital statistics, tuberculosis control, sanitary engineering, social hygiene, hospitals and laboratories, child welfare, and education.

The public welfare organization has as its manifold functions the relief of the poor in institutions and homes, the study of child welfare and mental hygiene, hospitalization of defectives, and the care of the delinquents.

Under county and rural planning are considered the systematization of highways and roads, regulation of traffic, erection of billboards, regulation of use of land, park system, recreational facilities, conservation of natural resources, and the promotion of reforestation.

Part II treats of the problem of finance or the operation of the county financial process. The economic appraisal includes values, topography, soil composition and quality of lands, use and productivity, fertility, water supply and natural resources, and accessibility to transportation and markets. Statutory provisions and administrative agencies are considered. The various processes requiring coördination consist of taxing power and raising of revenue, use of credit, selective process of officials, enactment of legislation, and issuance of administrative rules. The term "town-county-government," representing the local governing process of Virginia

towns, comprises all municipalities in the state below 5,000 in population. Except for a few special districts, as the sanitary district, the town is the one unit of local government with which the county uniformly maintains close relations throughout the state.

A commendable feature of the survey is its frankness; it discusses failures as well as successes. The material, with rich statistical evidence, is well presented; the type is clear and readable; and the subdivisions are logically captioned.

IRA V. HISCOCK

Through Early Childhood—The Care and Education of the Child from Three to Nine—By Arthur Whitefield Spalding and Belle Wood-Comstock. Mountain View, Calif.: Pacific Press Publishing Assn., 1930. 344 pp. Price, \$2.00.

This book is Volume Three of the five volume set of *The Christian Home Series*. The others are: Vol. I—Makers of the Home (General; for youth, the newly married, and parents); Vol. II—All About the Baby (Infancy—first 2 years); Vol. IV—Growing Boys and Girls (Pre-adolescence—10 to 13); Vol. V—The Days of Youth (Adolescence—14 to 20).

The authors' plan calls for study during each of the months of the year, the book being divided into 12 sections of 4 chapters each. In general, the first chapter in each section deals with government and environment, the second with nature study, the third with health, the fourth with social and religious training.

At the end is an appendix containing questions relating to the text, and problems for study and discussion; an index; and a bibliography.

This book is designed primarily for parents. It might well have borne, as a title, "Through Early Parenthood." It would have value too for elementary

school teachers and for young adults. It has throughout a strong religious and ethical content. In general it covers such factors as mental hygiene, sex education, nature study, cleanliness, nutrition, and the treatment in the home of simple ailments.

This is a valuable text, particularly for young parents. The information is given in a very interesting way, and is definite and simple enough in content and procedure to be really usable. An unusual production of a type quite different from the ordinary text on health teaching and child training.

CHARLES H. KEENE

Allergic Diseases. Their Diagnosis and Treatment—*By Ray M. Bal-yeat, M.D., F.A.C.P. Philadelphia: Davis, 1930. Price, \$5.00.*

The present volume was first issued in 1926 under the name "Hay-Fever and Asthma." In this edition the name has been changed and considerable new material has been added, particularly in methods of determining the cause of allergic conditions other than hay-fever and asthma, such as eczema, migraine, urticaria, and certain forms of mucous colitis.

The book is pleasantly written and is useful for the sufferer as well as the physician. It is abundantly and well illustrated. The fact that it has gone through three editions in approximately 4 years shows that it has a place and has given satisfaction. This last edition will be found even more useful than its predecessors. M. P. RAVENEL

L'Hygiène Publique en France—*By A. Landry. Paris: Librairie Félix Alcan, 1930. 173 pp.*

The book contains a chapter on maternity and infancy welfare work in France. As one of the most important measures for the welfare of mothers, the author points out the law of 1913, amended several times since, which pro-

vides for all women of small means a cash benefit paid from public funds for 4 weeks before and 4 weeks after confinement. A nursing benefit is also paid for 12 months, if the woman nurses her child. The number of women receiving these benefits has been greatly increased since the enactment of the social insurance law early in 1930.

Infant health centers are maintained by the municipalities as well as by private organizations.

The custom of placing out children with wet nurses is very prevalent in France, and a law has been in existence since 1874 which provides medical supervision over all such children. However, the administration of this law has been often criticised; it has been charged that the midwives and the parents often fail to make the necessary report to the authorities and thus escape supervision, and the examining physicians fail to carry out their duties properly.

Other chapters describe the organization of public health work in France and the teaching of hygiene in public schools. IRA V. HISCOCK

The Development of Physiological Chemistry in the United States—*By Russell H. Chittenden. American Chemical Society Monograph No. 54. New York: Chemical Catalog Co., 1930. 427 pp. Price, \$6.00.*

The author is in a singularly advantageous position to undertake this presentation. One might almost say that he officiated at the birth of physiological chemistry in the United States, and has been a directing force throughout its development. In his treatment two interrelated themes are carried along together through the work; one a history of the development of organized activity and personnel, the establishment and growth of laboratories, and the training of men competent to undertake productive scholarship in this field; the other

a history of the problems attacked and the results obtained by the various groups of workers. The latter phase is the more important contribution of the work. The development of the two themes is not entirely parallel, but they interlace and each augments interest in the other, though it is true that such treatment demands certain sacrifices both as to order of presentation and perspective.

While the development of the first theme becomes in the latter part of the book merely a sort of incomplete Who's Who among workers in the field of physiological chemistry, and will probably be of limited interest, the book as a whole should find a large circle of friends in all the various fields of both biology and of chemistry. One cannot help feeling that it has been written by one who possesses not only a broad view of the field and vision of its possibilities, but also a comprehensive and firm grasp of the work done in this country.

The stimulating character of the volume is brought out by the fact that while its function is not primarily to suggest problems, many will find that interesting unsolved problems seem naturally to come to mind while one is reading—not merely one here and there, but many. It is a picture done in bold strokes but the outlines of which are firm.

There is a good "Author Index," but one must depend on the "Contents" for subject matter. The printing and make-up are excellent. ALLEN E. STEARN

Handwörterbuch der psychischen Hygiene und der psychiatrischen Fürsorge—By O. Bumke, München, G. Kolb, Erlangen, H. Roemer, Illenau, E. Kaln, New Haven. (Berlin and Leipzig: Walter de Gruyter & Co.) vi, + 400 pp. 1931. Price, bound, M. 25.

The widening interest in the field of mental hygiene and the diversity and

social divergences of the professional groups and social and governmental agencies concerned with this remedial process distinctly call for a comprehensive work dealing with this subject. It is to be found in this monographic dictionary in which are assembled the facts and theories of psychiatry and of psychology as applied to the mentally aberrant.

The rubrics are relatively few, in fact only 72 in all. They range from alcohol to world philosophy, and include such topics as industrial hygiene, psychical hygiene, marriage, eugenics, nutrition, epilepsy, encephalitis, institutional equipment and care, and organization of institutions of various types and purposes, juvenile psychopathy, social life, sexual life, delinquency, constitution, Kultur, the occult, spiritism, opium laws, suicide, and suggestion.

C. A. KOFORD

Growth and Development of the Young Child—By Winifred Rand, R.N., Mary E. Sweeny, M.S., and E. Lee Vincent, Ph.D. Philadelphia: Saunders, 1930. 394 pp. Price, \$2.75.

Our modern knowledge of early childhood has been considerably enriched in recent years. This has been due largely to coöperative research carried on in connection with nursery schools or child welfare institutes. A pioneer in this field is the Merrill-Palmer School of Detroit. Out of the fertile experience of this school has emerged recently one of the most comprehensive and well balanced books on growth and development of the young child it has been our pleasure to read.

This book is unique in beginning with an exposition of the philosophy of family life which is fundamental to an understanding of the child in its modern relationships. "The Family and the Home as Backgrounds for the Growth of the Child" gives us, in the second

chapter, a basis for both the hereditary and environmental considerations which follow. There is presented a well proportioned picture of the child in its family relationships with critical evaluation of the conflicting elements in modern home life.

Throughout the book the physical growth and development of the child are so interwoven with its emotional and personality development that we feel from beginning to end it is the whole child in its multiform relationships with

whom we are most deeply concerned. The book bespeaks that intimacy and understanding of child life which only those who have been in sympathetic daily touch with the child could really picture.

The subject matter is arranged in such a way as to give a sense of proportion to the whole. Helpful references are found at the end of each chapter and a selected bibliography of 165 titles adds to the value of the volume.

HEALTH DEPARTMENT AND OTHER REPORTS

IRA V. HISCOCK

The Bellevue-Yorkville Health Demonstration, New York, N. Y.—The report of the Bellevue-Yorkville Health Demonstration for 1929 states that gross expenditures amounted to \$155,911.87, of which \$148,043.51 was contributed by the Milbank Memorial Fund. In accordance with plans initiated at the start of the demonstration for the peak of expenditures to be reached in 1929, a budget of \$150,000 was prepared for 1930, as compared with \$172,500 for 1929, adopted by the Board of Managers and approved by the Board of Directors of the Milbank Memorial Fund. This budget provides for assistance to the Health Department in the way of salaries for additional medical, nursing and clerical staff, and for special consultants in nutrition, mental hygiene, recreation, and social service to act as advisers to the nurses and in clinics.

At the beginning of the year the medical services carried on in the Bellevue-Yorkville Health Center consisted of a baby health station, a preschool clinic, an evening clinic for venereal diseases, the Yorkville chest clinic and a tuberculosis diagnostic service. In addition, three other baby health stations were maintained, at which there were 873 new registrations during the year. The number of children receiving three injections of toxin-antitoxin at the baby stations was 2,719. The children's clinic which had been conducted by the Association for Improving the Condition of the Poor was taken over on November 27 by the Health Department as an extension of its pediatrics service at the Health Center.

In January, 1929, a consultation service was opened for private physicians of the city, to aid them in making a diagnosis of patients suspected of having tu-

berculosis. Only patients sent by their physicians are examined at these three weekly sessions. No advice or information is given the patient, but a full report is made to the physician.

The number of nurses in the combined Bellevue and Yorkville Districts, who also serve territory out of the Bellevue-Yorkville area, averages 37. In the Yorkville District, the generalized system of nursing was introduced in 1929; in the Bellevue District, nursing organization is based on the specialized plan, each nurse being assigned to work either in school hygiene or in preventable disease work.

The statistician of the New York Tuberculosis and Health Association acts as consultant to the demonstration. Monthly reports are prepared on the volume of public health work in the area. The special undertakings of the statistical staff during 1929 include tabulation of the physical defects among school children examined, a brief analysis of new registrations during 1928, a study of the nurses' reports by principal lines of services to show time distribution, the case load, and a study of the number of household contacts to the tuberculosis cases under the care of the Yorkville clinic.

General health education and publicity in the demonstration area for 1929 included the distribution of over half a million pieces of printed matter, including 12,000 posters, to residents, doctors, dentists, schools, stores, clubs, health agencies, the publication of six issues of *Health News*, a picture newspaper, and the coöperation in the city-wide campaign for immunization against diphtheria. Three times as many children received the three toxin-antitoxin inoculations in 1929 as in 1928 at the baby health stations. The campaign in the

interest of periodic health examinations was also continued, in coöperation with the County Medical Society and the independent medical societies located in the district. As a result of 30,000 cards being distributed to school children, urging a yearly health examination, the health center was deluged with children asking for examinations. An emergency service was established to take care of those who had no physician, and who came accompanied by their parents, and 1,171 children were examined at a cost of \$.35 per child.

Health education in the schools has been developed by the organization of close relationships among principal, doctor, nurse and teachers, the immediate responsibility within the schools being that of the assistant principal. New developments have been regular conferences with the special teachers of health education, assistance with the teacher-training courses for grade teachers, development of a junior high school program, and the beginning of a more definite study of behavior problems.

The recreation problems of Bellevue-Yorkville resolve themselves around the improvement of the conditions within the district, which include but a small amount of safe outdoor play space, and the inability of a large number of children to enjoy vigorous play. A district recreation conference held at the health center in the spring of 1929 recommended possible plans for use, and secured the opening of a summer playground. Emphasis was placed on day outings in order to compensate for the inadequacy of play space within the district. Most of these were to parks, and some were for education in connection with the safety-and-health campaign in summer playgrounds. An important part of the recreation work in 1929 was the directing of recreation classes in three Catholic schools of the district.

By an arrangement between the dem-

onstrator and the Henry Street Visiting Nurse Service, a consultant in mental hygiene was added to the staff at the health center in April, 1929, the activities being twofold—those with the nursing group as a whole, and those with the individual nurse working on a special problem. At the close of the year, about 125 active mental hygiene cases were being carried by the Henry Street nurses in the district, representing a wide variety of problems which varied from many cases of poor health habits to neuroses, psychoneuroses and a few definite psychoses.

Montclair, N. J.—The 1929 health audit of the town of Montclair, N. J., is the yearly report of the work carried on by the Department of Health. Montclair had an estimated population in 1929 of 40,264. The resident death rate was 9.4 per 1,000, and the resident infant mortality rate for 1929 was 43.5, for which considerable credit is due to the prenatal and postpartum activity carried on in connection with Mountain-side Hospital by the Nursing Service of the Red Cross. Tuberculosis showed a slight decrease over 1928.

Of 445 re-Schicked school children, 298, or 67 per cent, were found immune; 148 were reinoculated. Of the 678 school children Schick tested for the first time, 212, or 31 per cent, were found to have a natural immunity. In the preschool clinic, 560 children received the toxin-antitoxin inoculations. The chest clinic, opened in 1905 by the Montclair Tuberculosis Committee, and since 1912 conducted jointly by the committee and the Department of Health, has been taken over entirely by the latter. The total attendance during the year was 286, the total number of patients 109, of whom 54 were new. Seventy-six patients were taken to the sanatorium.

The department passed an ordinance in 1929 which will limit the sale and

slaughter of poultry only to those having first class sanitary establishments. To insure against the danger of undulant fever, a letter was sent to all of the producers and distributors of raw milk warning against the menace and advising agglutination testing of herds.

Pittsfield, Mass.—In the 1929 annual report, the health officer of Pittsfield records an infant mortality rate of 68.7 and a neonatal rate of 42.6 in this city of 51,000 estimated population. During the first 3 months of the year, an increase in influenza cases reached epidemic proportions, 81 cases occurring at that time. There were but 4 cases during the remainder of the year, the deaths for 1929 totalling 12. There was a slight increase in the number of cases of diphtheria and scarlet fever, but no case of smallpox was reported.

Tuberculosis cases (29) and deaths (18) reached the lowest figure that has been recorded since there has been adequate reporting. Twenty-three of the 29 cases were hospitalized. The average number of farms supplying milk to the city was 170; 199 dairies were inspected and 501 samples of milk collected. The number of cows under test in the city exceeded 85 per cent—thus Pittsfield is eligible to be classed as a modified tuberculosis-free area.

The spring round-up was held in June, and a visit was made by a health department nurse to the parents of each child expecting to enter school in the fall of 1930. Parents were advised to take their children to a physician to be examined for medical defects and to be vaccinated. The clinic at the health department was held to accommodate those families who were without a family physician or who could not afford to visit a private physician. May Day activities were confined to dental work. The dental hygienist examined 2,007 children, and 1,361 were found to have dental defects. The total number of

corrections accomplished by this one examination was 2,364.

The 1929 budget contained an appropriation for mosquito control, and a member of the Harvard School of Public Health took charge of this work with favorable results. The report concludes with an appraisal of the city's health activities, following in detail the *Appraisal Form for City Health Work* of the American Public Health Association.

Hawaii Dental Survey—A comprehensive survey of the dental problem in the Territory of Hawaii was made in 1930 under the auspices of the Department of Public Instruction of the Territory and the Strong Foundation. The report of 158 pages by Guy S. Millberry, D.D.S., F.A.P.H.A., is broad in scope and of special interest to public health administrators and to those engaged in dental hygiene work.

This report describes in detail a community dental hygiene program which is probably unsurpassed in the country, and makes recommendations for future development. Many photographs, charts and statistical tables are presented, together with survey forms which should prove useful in studying dental programs elsewhere.

The 12 chapters of the report review the development of dental hygiene work and deal with important problems of legislation, organization and personnel, policy and procedure, records, finance, objectives and accomplishments, the dental profession, the press, research, and advanced instruction.

A school of dental hygiene was organized in 1921, in conjunction with the normal school, and three classes were graduated. All but one of the graduates entered school service in the territory. In 1920, the Honolulu Dental Infirmary was organized, and this work was later moved to a convenient wing at Palama Settlement where 5 dental operators were employed. In 1922, the

division of dental hygiene was organized in the Department of Public Instruction. In 1929, 98.8 per cent of the children in the public schools received instruction in dental hygiene or care. The dental hygiene division is under the direct control of a supervisor who reports to the superintendent of the public school system. In Honolulu, this work in the schools is correlated with treatments in Palama Settlement. "The influence of the program has extended beyond the schools into all territorial institutions and many private ones, a further endorsement of its value. . . . The passing of the Act of 1922, creating the Division of Dental Hygiene under the jurisdiction of the Superintendent of Public Instruction, is one of the outstanding pieces of dental health legislation in the country."

Montreal, Que.—The 1929 report of the department of health opens with a table of contents and an organization chart which shows the bureaus, personnel and activities of the department. The chart also indicates that the department of health functions under an executive committee with an advisory board of health of 9 members consisting of the chairman of the executive committee and the director of health *ex-officio*, 3 members of the city council, 2 members each of the faculties of medicine of the University of Montreal and of McGill University.

On the basis of an estimated population of 762,000, the per capita expenditure for the section of hygiene under the department of health amounted to \$.57, while that for municipal assistance was \$1.68. Other expenditures of the department included pensions and annuities, and allocations of \$20,000 to universities. A birth rate of 26.79 and a death rate of 13.9 are recorded. The infant mortality rate was 132.3. Comparative data for 10 previous years are presented. Many interesting statistical

tables are accompanied with descriptive text.

The National Committee for Mental Hygiene in Canada organized in 1929 a section for the Province of Quebec. The executive committee and the department of health inaugurated a program in the schools of the Catholic School Commission of Montreal, which is later to be operated in the Protestant schools. Two psychiatrists and two nurses with psychology training were employed to work with and instruct the physicians and nurses of the department of health engaged in school medical inspection work. During the school year the work was carried on in 17 schools attended by 12,500 pupils.

An agreement became effective between the school commissions and the department of health to establish close cooperation in school medical inspection. During 1929, 3,221 children were given three antitoxin Ramon inoculations as a protection against diphtheria. A Schick test was given these children 4 months after the last injection, and if positive, a fourth injection was given. A total of 15,337 smallpox vaccinations were given by physicians in the divisions of child hygiene and communicable diseases.

By July, 1929, 37 municipal baby clinics were in operation, an increase of 20 over the previous year. These clinics are operated by the staff of medical inspection of schools. In school sub-districts where a baby clinic exists, the school nurse is in charge with an assistant nurse (not a graduate). The other clinics are intrusted to graduate nurses, each of whom is in charge of two clinics. Medical inspectors serve one or two clinics and each of 11 part-time physicians have a clinic. There were 37,496 consultations in clinics with 33,568 home visits. Besides these municipal clinics there are 34 independent baby clinics in the city, 18 under the management of the Federation d'Hy-

giene Infantile, and 16 under the Child Welfare Association. These latter clinics submit monthly reports to the department of health.

Brookline, Mass.—During 1929, 509 births were recorded, of which 398 occurred outside of town to residents. There were 525 deaths in this community of 47,100 population, but 157 of the decedents were non-residents. There were 5 cases with no deaths from diphtheria. During the 6 years previous to 1923 when immunization work was undertaken, there were 288 cases and 11 deaths from diphtheria. During the 6 subsequent years, there were 51 cases with no deaths from this disease. An infant mortality rate of 43.3 is recorded.

A health bulletin has been published quarterly and distributed by the Police

Department to every house in the town. The purpose of the bulletin is to promote education in health matters and to inform residents of the quality of milk sold by the various dealers.

A decision of the Boston Medical Milk Commission made it possible for certified milk to be sold as a pasteurized product as well as raw. Specifications for school milk were revised to provide additional safeguards, including a requirement that the producing animals be tested and certified as free from contagious abortion. The milk is processed by the spray vat system, and the jars are sterilized in an automatic thermostat-controlled machine and automatically filled and capped to avoid human contact with the milk. The average dairy score was 93.8 and the average bacteria count of this school milk was 11,272.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON. PH. D.

Public Health Service Activities—This inclusive and most readable account of the varied activities of the U. S. Public Health Service will give just the right information to any sanitarian who wants to tell others what the federal health authorities do.

ANON. The Work of the United States Public Health Service. Pub. Health Rep., 46, 6: 269 (Feb. 6), 1931.

Advances in Tuberculosis Research—Outlining the progress in tuberculosis prevention and prepared for general practitioners of medicine, the paper deserves study by sanitarians as well.

BALDWIN, E. R. A Review of the Progress of the Control of Tuberculosis and Advances in Its Pathology and Bacteriology. New York State J. Med., 31, 4: 195 (Feb. 15), 1931.

Health Institute Costs—Painfully frank is this priceless story of what it costs to conduct a first-class public health institute and what results may be expected therefrom. Food for thought alike for the ambitious and the unambitious administrator.

Public Medical Service in England—A straightforward and apparently unprejudiced account of the scheme for medical service for the industrial population. How the service affects public health is touched upon.

HARRIS, R. W. National Health Insurance Medical Service in Great Britain. *Canad. Pub. Health J.*, 22, 2: 55 (Feb.), 1931.

Hunger Striking Children—Most children who present the problem of anorexia are of the linear type, fatigued and irritable. Diets high in fat are contraindicated for such children. A quart of fruit juices in place of milk, and a low residue, high vitamin content diet, combined with a regimen of rest, have proved successful.

LUCAS, W. P., and PRYOR, H. B. Factors Involved in Combating the "Hunger Strike" in Children. *Am. J. Dis. Child.*, 41, 2: 249 (Feb.), 1931.

Delinquent Venereal Cases—Health officials perplexed by the prob-

lem of delinquency in venereal disease clinic attendance will find much to console them in this British discussion of "defaulters" in the Glasgow clinic.

MACGREGOR, A. S. M. The Problem of the Defaulter in V. D. Treatment Schemes. *Med. Off.*, 45, 5: 49 (Jan. 31), 1931.

Student Health Problems—Two questions are answered: should definite health instruction be included in the curriculum? and what are the desirable relationships between health and physical education?

OBERTLUFTER, D. Two Problems in Health Education. *J. Health & Phys. Ed.*, 2, 2: 3 (Feb.), 1931.

Nutrition and Growth—A group of underweight children on a special dietary of milk, whole-grain cereals, vegetables and fruit (meat and eggs excluded, making a preponderance of base-forming elements) made better gains, as judged by several anthropometric measures, than did a control group on a representative American dietary.

ROSENBERG, L. C. Malnutrition in Children. *Am. J. Dis. Child.*, 41, 2: 303 (Feb.), 1931.

Preventing Colds at Cornell—Students unusually susceptible to colds were divided into a cold prevention class and a control group. A reduction of about 50 per cent in colds was accomplished. If you would like to know how and what the possibilities in cold prevention are, read the article.

SMILEY, D. F., and MAUGHAN, G. F. Cold Prevention Work at Cornell University. *Sci. Monthly*, Mar., 1931, p. 235.

Industrial Nursing—A series of brief articles on industrial nursing problems make up the bulk of this issue of the *Public Health Nurse*. They are too numerous and brief to be mentioned separately in this bibliography, but all are well worth study.

NEWS FROM THE FIELD

EDWIN J. BANZHAF

DR. EDWIN J. BANZHAF died suddenly of heart disease on March 17.

After graduation from Lawrence College he continued his studies at Columbia University where he received a degree of Doctor of Philosophy. Shortly after leaving Columbia University he became a member of the staff of the bacteriological laboratories of the Department of Health of the City of New York. For a period of 27 years he has been in charge of the chemical side of the production of biological products. His first important work was on methods of improving the refining of diphtheria antitoxin. This was published in 1907.

The endeavor to devise methods better to refine and concentrate the various antiserums became his life work. These included diphtheria and tetanus antitoxin, antimeningococcic, antipneumococcic and antipoliomyelitis serums.

During the past three years he spent a great deal of time trying to eliminate the chill producing substances from antipneumococcic serum. His efforts met

with marked success. His duties were gradually widened until he assumed control not only of the refining and concentrating of the different serums but also of some of the preventive vaccines, such as diphtheria toxin-antitoxin and toxoid. In time he also undertook the supervision of the preparation of the biological products for the final distribution to the physicians. He became one of the Assistant Directors of the Laboratories, January 1, 1910.

As his experience increased, he became widely known as probably the one in America who knew most about the practical refining of antibodies. A number of the biological plants in this part of the country so appreciated his knowledge that they appointed him a consultant.

Dr. Banzhaf was a scientist of the first order. He was modest and retiring in his disposition but made many warm and lasting friendships. His death is a very great loss to the laboratory in which he worked and to the people of the country. Not only those who were his colleagues but all workers in his field will miss him greatly.

NEW MOTHER'S DAY

WOMEN'S clubs throughout the country will join in an appeal on Mother's Day, May 10, to obtain adequate maternity care for mothers in the United States. Details may be had from the Maternity Center Association, 576 Madison Avenue, New York, N. Y.

SWISS EXHIBITION FOR HYGIENE AND SPORT

THE first Swiss exhibition for Hygiene and Sport, the "Hyspa,"

will be held at Berne from July 24 to September 20. The Exposition buildings are now being erected on the spacious Viererfeld for the following groups: Climatology and Balneology; Home and Residence; Diet, Food and Beverages—A Model Dairy; Clothing and Styles; Care of the Human Body and Sport; Protection of Workers, Social Welfare and Insurance; Infectious Diseases; Hospitals and Nursing; Medical Research and Medicines; Hygiene of Youth and Welfare of Mothers; Hygiene in Traffic; Mankind, including

Anatomy and Physiology—the history of medicine and natural sciences, etc.; Statistics; Army Sanitary System; Industry and Trade.

NATIONAL TUBERCULOSIS ASSOCIATION ANNUAL MEETING

THE annual meeting of the National Tuberculosis Association will be held at Syracuse, N. Y., May 11 to 14.

In conjunction with this meeting the Executive Committee has proposed a "pilgrimage" to Saranac Lake, which is only about 200 miles distant, and would like to hear as soon as possible from members and friends who would be interested in this pilgrimage.

NEW ENGLAND HEALTH INSTITUTE

THE New England Health Institute will be held in the Eastland Hotel, Portland, Me., April 20 to 23, 1931. The program is arranged in 10 sections. The sections and the chairmen of each are as follows:

- | | No. of
Lectures |
|---|--------------------|
| I Public Health Administration—Dr. Charles F. Dalton, Secretary of Board of Health, Burlington, Vt. | 5 |
| II Preventable Diseases and Cancer—Dr. Howard A. Streeter, Health Officer, Manchester, N. H. | 7 |
| III Sanitation and Engineering—Prof. Ira V. Hiscock, Yale School of Medicine, New Haven, Conn. | 6 |
| IV Tuberculosis—Dr. Alton S. Pope, Director, Division of Tuberculosis, State House, Boston, Mass. | 6 |
| V Venereal Diseases—Dr. Charles A. Weaver, Director, Division of Venereal Disease Control, Concord, N. H. | 5 |
| VI Child Hygiene—Charles F. Wilinsky, M.D., Deputy | |

Health Commissioner in charge Child Hygiene and Health Units, Boston Health Department, Boston, Mass.

VII Mental Hygiene—Dr. Carl D. Bond, Pennsylvania Hospital, Institution for Mental Hygiene, Philadelphia, Pa.

VIII Health Education—Prof. C. E. Turner, Massachusetts Institute of Technology, Cambridge, Mass.

IX Vital Statistics—Dr. T. F. Murphy, Chief Statistician for Vital Statistics, Bureau of the Census, Washington, D. C.

X Public Health Nursing—Harriet Leck, R.N., Visiting Nurse Association, Hartford, Conn.

Dr. C. F. Kendall, Commissioner of Health, is director of the New England Health Institute and Dr. W. L. Holt of the Maine State Department of Health is chairman of the program committee. Preliminary announcements will be sent out early in March to all physicians, dentists, nurses and health workers. The program is nearly complete and will be mailed some weeks later to all members of the A. P. H. A. in New England and others interested.

Among the prominent speakers will be Dr. T. J. Parran, Dr. William J. French, Dr. C.-E. A. Winslow, Dr. S. D. Kramer, Dr. F. L. Hoffman, Frank Kiernan, Dr. Matthias Nicoll, Prof. C. E. Turner, Dr. R. B. Kerr, Dr. T. F. Murphy, and Dr. H. L. Lombard.

TEXAS SHORT SCHOOL
DATES for the Ninth Texas Sanitarians Short School have been designated for November 9-14, inclusive, at Houston, Tex. Those in charge

are: Dr. H. K. Read, President of the Texas Public Health Association; Dr. Allen C. Hutcheson, Director of the School; C. F. Browning, General Chairman; and E. G. Eggert, Secretary.

COLLEGE HYGIENE

THE National Conference on College Hygiene to be held at Syracuse University, Syracuse, N. Y., May 5 to 9, under the joint auspices of the Presidents' Committee of Fifty on College Hygiene, The American Student Health Association, and the National Health Council, aims to come to an agreement on desirable minimum standards for the teaching and practice of college hygiene. Dr. T. A. Storey of Stanford University is Chairman of the Conference and Dr. H. S. Diehl, Dr. Walter Brown, Dr. Joseph Raycroft and Dr. D. H. Smiley head the four sections on Health Service, Health Teaching, Physical Welfare Activities, and Miscellaneous Problems. Reduced rates on the certificate plan have been granted by the railroads.

MICHIGAN PUBLIC HEALTH ASSOCIATION

THE Tenth Annual Conference of the Michigan Public Health Association and the Michigan Department of Health was held in Lansing, January 7-9.

The officers elected for 1931 were as follows: Dr. C. C. Young, President; Dr. Merrill E. Champion, Vice President; Dr. W. J. V. Deacon, Secretary-Treasurer; Dr. C. C. Slemons, Representative on the Governing Council, A. P. H. A.

RESEARCH FELLOWSHIP OFFERED BY NATIONAL TUBERCULOSIS ASSOCIATION

THE National Tuberculosis Association announces a limited number of fellowships in social research as related to tuberculosis, open to graduate students who have had special training in statistics, social science, or public health.

Preference will be given to candidates who are interested in pursuing research in public health after the completion of this fellowship. Interested candidates should write to Jessamine S. Whitney, Statistician, National Tuberculosis Association, 450 Seventh Avenue, New York, N. Y., for further information.

NORTHERN CALIFORNIA PUBLIC HEALTH ASSOCIATION

THE annual meeting of the Northern California Public Health Association was held in the Women's City Club in San Francisco on February 7 with an attendance of over 100.

The following officers were elected: President, Guy S. Milberry; First Vice-President, Thomas A. Storey; Second Vice-President, Dr. W. H. Kellogg; Treasurer, Mary E. Davis; Secretary, Walter H. Brown.

NEW YORK SPECIAL HEALTH COMMISSION

NEW York State, through a Special Health Commission appointed by Governor Roosevelt, has recently issued a report the recommendations of which have been incorporated in a Bill now before the state legislature, leading to a new forward-looking program of public health administration.

Dr. Livingston Farrand, President of Cornell University, as Chairman of the Commission has issued a statement indicating that the major recommendation of the Commission is that a county board of health be organized in each county in the state in place of the present system of small township and village health units.

Other important recommendations of the Commission include the provision for additional state tuberculosis sanatoriums, an enlarged cancer program, more adequate facilities for the discovery and care of crippled children, increased authority over the sanitary control of public water supplies and stream

pollution, and provision in the program of county boards of health for the diagnosis and treatment of the venereal dis-

eases, more extensive health measures for mothers and children and better trained public health personnel.

PERSONALS

DR. GEORGE W. GALE, who is 94 years old, is planning to retire as a member of the Saugus (Mass.) Board of Health when his term expires after nearly 35 years' service.

COL. MATTHEW A. DELANEY, Army Medical Corps, Chief Medical Adviser to the Governor General of the Philippines, will on May 1 become Chief Surgeon, 5th Corps Area, Columbus, O.

VERANUS A. MOORE, M.D., D.V.M., D.Sc., Dean Emeritus of the New York State Veterinary College of Cornell University, died on February 11 as a result of cardiac weakness following a major operation. Dr. Moore has been a member of the American Public Health Association since 1896, and a Fellow since 1922.

DR. HAROLD RYPINS of New York was elected president of the Federation of State Medical Boards of the United States.

DR. WALTER W. LEE, formerly with the State Department of Health of Connecticut, was recently appointed District Health Officer in the Berkshire District of Massachusetts.

JOSEPH P. DAY was reelected president of the Judson Health Center, 237 Thompson Street, New York, N. Y.

LOUIS CARLETON BULKELEY of Shreveport, La., passed away on December 24, 1930. He was a Fellow of the American Public Health Association.

DR. R. E. HICKEY on February 1 became Director of the Bureau of Communicable Diseases, of the Department of Health, Milwaukee, Wis., filling the position vacated by Dr. M. R. French, now of the New York State Health Department.

J. ROSSLYN EARP, Dr.P.H., formerly Director, Department of Health, Antioch College, Yellow Springs, O., was recently appointed Director, Bureau of Public Health for the State of New Mexico. He succeeds George S. Luckett, M.D., who resigned several months ago.

WADE H. FROST, M.D., has been appointed Dean of the School of Hygiene and Public Health at Johns Hopkins University, succeeding W. H. Howell, Ph.D., M.D., who has been Director.

CONFERENCES

April 8-11, American Physiological Society, Montreal, Can.

April 8-11, American Society for Experimental Pathology, Montreal, Can.

April 8-11, American Society for Pharmacology and Experimental Therapeutics, Montreal, Can.

April 8-11, American Society of Biological Chemistry, Montreal, Can.

April 8-11, Federation of American Societies for Experimental Biology, Montreal, Can.

April 12-15, Tenth Annual Convention, International Society for Crippled Children, Cleveland, O.

April 13-16, American Red Cross, National Convention, Washington, D. C.

April 14-16, Tennessee State Medical Association, Knoxville, Tenn.

April 14-20, World Conference on Work for the Blind, New York, N. Y.

April 15-18, American Orthopedic Association, Memphis, Tenn.

Public Health Service— A Sound Investment*

LOUIS I. DUBLIN, PH. D., F. A. P. H. A.

Statistician, Metropolitan Life Insurance Company, New York, N. Y.

PUBLIC health work in America has developed with little regard to its cost or its value as an investment. It has grown primarily out of a generous desire to care for widespread illness and to check the spread of the more spectacular infectious diseases. Every epidemic of yellow fever, smallpox, and cholera, strengthened the limited powers of the health authorities. The activities they inaugurated were common sense reactions to the pressing needs of a dangerous situation. Later, esthetic considerations played their part. The growth of our cities demanded the removal of rubbish and of other wastes and this soon became a recognized function of many health departments. It was only in comparatively recent years that such activities as public health education, child hygiene, nursing, infectious disease control, and the other functions which constitute the routine of our best departments today, were added one by one; but even where the work has been most extensively organized, there has been very little recognition of the economic advantages accruing from this type of service.

No wonder then that the public health program has been extended in a halting fashion and has nowhere reached its full potentialities. The claims of health officers have not always been particularly convincing. There has been considerable hesitation about spending public funds on plans which often seemed tentative and experimental in character. To justify the widening scope of health service, it is intended in this paper to consider whether it is not, among other things,

* Presented at a General Session of the American Public Health Association at the Fifty-ninth Annual Meeting at Fort Worth, Tex., October 30, 1930.

a sound business proposition. The time has now come when we can evaluate in monetary terms the claims of public health effort. Public health work can be justified very much as are other communal services such as the paving of our streets, the building of roads and the establishment of fire departments. These undertakings pay for themselves and bring a return more than sufficient to meet their cost. I propose to show that certain phases, at least, of the public health program are among the most profitable investments in which a community can place some of its funds. In fact, it is not difficult to prove that the financial returns are often out of all proportion to the cost of the effort, and justify much larger outlays than even the most progressive communities have made.

VALUES TO DEPENDENTS AND RELATIVES

Everyone will agree that human life has value, not only sentimental, but actual economic value. The view that men, women and children should be looked upon as community assets is rapidly spreading throughout the civilized world. Learned books have been written to show that human life in the aggregate is the community's greatest asset, far transcending material possessions of all kinds. There is, in the first place, good indication that human beings have economic value based on the fact that it costs a great deal of money to raise them to the point where they function as productive individuals. Parents ordinarily spend large sums of money to bring their children into the world, to feed, house, clothe, educate them, and to give them all the other things that are a necessary preparation for good citizenship. Having in mind that large group of people who constitute the average of our population, it costs about \$10,000 in actual cash to provide even the very modest requirements of a growing child up to the age of 18. There are, of course, large numbers of children on whom much more is spent; but, broadly, one can consider \$10,000 as a figure fairly representing the cost of bringing a child to maturity in the United States today.

Now it may be argued that money spent on an individual is no measure of his economic value, and perhaps a good case could be made out for that point of view. Parents spend money on their children not because they expect a good return on the investment, but because they love them and wish to serve them. After all, the best proof that human beings have economic value lies not so much in their cost but rather in their capacity to produce. We shall avoid debatable ground in attacking the question of the money value of human beings by considering them in their specific relationship to other individuals and on

this basis determine their value to their relatives. The commonest relationship is that of the breadwinner to a dependent wife and child. The average wage earner has very obvious money value to such dependents, and it is ordinarily a relatively simple problem to calculate the value of this wage earner to his dependents. It will depend upon the man's annual earnings and his age, for his age determines his probable after life-time.

Dr. Lotka and I, in our recent volume, *The Money Value of a Man*, have produced a series of tables which give the money value for persons of various earning capacities at different ages of life. For example, the money value to his family of a man 30 years old in the \$2,500 income class is \$31,000; for one in the \$5,000 income class, it is nearer \$50,000. In other words, it would take that much money put at interest at 3½ per cent to produce for a body of persons at a stated age, the total net income which they would earn for the rest of their natural lives. For those belonging to the higher income classes, the economic values to dependents are very much greater.

Such economic value of human beings to their dependents is well understood and is universally granted by the laws and our courts. Whenever an injury is done to an individual through the fault of another, he or his dependents can collect damages which bear some relation to his economic value. More and more, the courts are inclined to take into consideration authentic figures of economic value and make them the basis of awards, rather than leave the adjudication to sentiment or to the effect of eloquent pleas to juries. The main point here is that human beings, men, women, and children, have economic value as individuals—and in the aggregate such value transcends all other values. There is no greater asset in any community than the human beings who make it up. When some of them are destroyed or put out of action, the community thereby loses some of its wealth. When they are preserved and brought up to maturity with the least amount of wastage, the community profits and becomes enriched through the added productiveness of its citizens.

LEGAL ASPECTS

An interesting and instructive application of this principle that human life has money value is found in the legal cases now rapidly accumulating in which damages have been awarded against private companies and cities which have supplied drinking water that was polluted and hence responsible for typhoid fever cases and deaths. It is now a settled principle of law in the United States, confirmed by the Appellate Court in a case against the City of Albany, that a private com-

pany or a city acting as a corporate body which supplies water for human consumption must exercise every reasonable precaution to render it safe. If it is negligent in this obligation and injury results to a consumer, it may be sued for damages.

The first legal case on record, apparently, followed an epidemic of typhoid fever in Ashland, Wis., in 1893-1894 which was directly traced to an infected water supply. The widow of one of the victims brought suit against the water company and was awarded \$5,000 damages. Even more famous in establishing this principle of law was the case of *Keever vs. the City of Mankato, Minn.*, in which damages to the amount of \$5,000 were awarded in 1910 against the city because of a typhoid fever death resulting from the pollution of the water supply. A number of similar cases have occurred since then; but on the whole these important precedents have received much less attention than they deserve from health officers.

In 1920, following a typhoid epidemic in Pittsburgh, Calif., the Supreme Court of that state awarded nearly \$33,000 in damages to 19 plaintiffs who had suffered from the disease. The largest penalties on record are those against the City of Olean, N. Y., which two years ago suffered from an epidemic of typhoid fever in which 212 cases and 18 deaths occurred. It was necessary to vote a bond issue of \$350,000 in order to pay the claims; and in 1930, this same city requested permission of the state legislature to issue bonds for an additional \$75,000 in order to cover its losses.

It is true that these cases all center around the responsibility of the community to protect citizens from typhoid fever. To what extent is this principle of responsibility applicable to other situations in which the municipality has taken over the control of community needs? It is a fact recognized by everyone that in the complex life of our cities, the individual is quite unable to protect himself and his children against infection from a host of diseases and conditions. This is the justification and warrant for the health department. Consequently, the individual looks to the organization of his city or county to protect him. In so far as such obligations are assumed by the organized agencies of government, the question may well be asked whether injury resulting from neglect of such responsibility may not justify damages in the form of compensation to the injured parties. While there have been no such cases, and while there may be legal considerations which rule out such claims, it would seem that this possibility should be carefully considered. Once the principle of financial responsibility is widely established, public health work will be placed on a more permanent and secure basis than it has hitherto enjoyed.

PROGRESS IN HEALTH CONSERVATION

I raise these questions because they illustrate in dramatic form the thesis which I am elaborating, namely, that human life has great economic value and that public health work, as it has developed, has long been and is now becoming to an ever greater degree a conserver of such values. But long before the thesis that public health work may be regarded as a public investment was elaborated and before cases of damages occurred, proof had accumulated that the neglect of the public health was poor economy. The history of sanitary effort, as it has developed during the last 50 years, is replete with achievement. Though everyone is more or less familiar with the progress of the health conservation movement, it may be desirable to rehearse some of the principal public health activities which have resulted in a widespread reduction of sickness and of premature death.

First of all, typhoid fever has been almost completely controlled in the United States. It is but a short time ago that epidemics of this disease ravaged the countryside and took a heavy toll even in our large cities. As late as 1900, the death rate from this cause was 36 per 100,000 of population in the U. S. Registration Area, and it was unquestionably very much higher in the rural non-registration states. Each death represented at least 10 cases. Many readers are old enough to recall the epidemics of typhoid fever in Cincinnati, Philadelphia, and Pittsburgh, and any number of other communities, in which thousands of cases and hundreds of deaths occurred because the water supply was polluted and little or nothing was done to prevent the spread of the disease through secondary infection. It was perfectly clear that such conditions could not long continue if the cities were to grow and prosper as residential and business centers. Finally excellent water systems were installed in the larger cities and as a result of better supervision, and chlorination of water when necessary, the typhoid fever rate dropped in an amazing manner.

The death rate was only 5.5 per 100,000 in 1927; for the urban part of the population, it was only 3.0. In some communities like New York, where hundreds of millions of dollars were spent on the water system, barely a case of typhoid fever or a death which could be traced to the city's water supply has occurred in years. Because of its wise sanitary precautions the city, like so many others, has been enabled to grow to an extent consistent with its economic possibilities. Altogether, the experience has been so favorable that there is little danger at this time that any large community in the country will be tempted to skimp on the expenditure necessary to supply its citizens with plenty of good water. It does not require damage suits to prove

that this kind of public health work pays for itself and handsomely.

Other conditions have been attacked by the health authorities with similar success. The control of malaria is an excellent illustration of the large financial returns which have resulted from well conducted public health effort. This disease was until recently widespread over the southern states. It lay like a heavy weight on the country, sapping the energy of large populations and in certain areas rendering them virtually nonproductive. Then came the new technic for the study and eradication of the disease. This was launched largely under the direction of the public health movement and demonstrated not only that malaria could be controlled but that it cost a sum so small as to be out of all proportion to the value of the lives thus protected. Results of malaria campaigns are quickly discernible. In a number of demonstrations, the morbidity rates from malaria have been reduced to a third in the short period of two or three years.

The effort of the International Health Board of the Rockefeller Foundation in this field has been extremely significant. According to its reports, the usual methods of drainage, screening, and treatment of infected cases, may be carried out at a per capita cost of from \$.45 to \$1.00 a year. This amount is, of course, only a fraction of what is gained through the reduction of cases and the prevention of deaths. In fact, it is not too much to say that the campaign against malaria has resulted in a complete change in the economic and social life of large areas in our southern states. Many of the new industrial efforts, so characteristic of the new South, are entirely predicated on the elimination of malaria, as well as of typhoid fever and hookworm; the 3 scourges which have so heavily afflicted this part of the country.

Successful results have, likewise, attended the campaigns of health departments during the past 25 years to reduce infant mortality. By means of popular education and the service rendered in baby health stations, the mortality of infants has been reduced to less than half of what it used to be; so that now the infant mortality rate is under 7 per cent. There has been no greater contribution to the welfare of the community than the saving of this number of potentially valuable human lives; nor has this effort of the public health movement been limited to the first year of life. The same services have led to marked reductions in the mortality and morbidity of children in the preschool years from diarrhea and enteritis and other infections. The whole campaign of child welfare has been built around an attempt to safeguard the infant and to stimulate the growth of children into healthy and productive citizens. The child health campaign will on careful analysis be found to have paid for itself many times over.

A claim equally far-reaching can be made for the campaign to control tuberculosis. I need not recount all the efforts which have gone into this movement. The work has not been done by health officers alone; but it is to the everlasting credit of a few far-sighted public health authorities that the entire program was organized and other groups in the community were encouraged to aid the movement. Altogether, an amazing success has been achieved. In the short period of 30 years, the death rate from tuberculosis has been reduced to about one-third of what it was, and at present the rate of decline is faster than ever. The gains to the country economically and socially are incredibly large. Tuberculosis used to be one of the chief causes of poverty. Social workers were in the habit of tracing the origin of many of their relief cases to its ravages. Today, relatively few such cases come to their attention—other conditions now cause the trouble.

The more recent efforts of health departments also have important economic aspects. Less than a decade ago, they initiated a campaign to eradicate diphtheria, the intensive development of which goes back only three or four years. Already this disease is being erased from the list of community health problems. Active campaigns of immunization have been strikingly successful. In some cities, the current figures show a reduction of 50 per cent and more during the last year or two. The death rate which in 1910 was 21.4 per 100,000 of population in the registration area will this year probably be close to 5.0. Apparently, the complete elimination of diphtheria is only a matter of a few more years. All that is required is the effective routine of educating parents to immunize every young child.

I could refer to the promising efforts to reduce pneumonia, to the newer work against certain forms of heart disease, and the venereal diseases, all of which show real achievement and point to even greater success in the future. Possibly, however, the largest gains will come from the efforts of health departments to inculcate a new conception of personal health among the great mass of the people and to teach the lesson of preventing disease by keeping physically fit.

Whether the work is directed to the control of infection or takes the form of education, the result is pretty much the same. Life is being guarded from disease and premature death and life is being conserved on an enormous scale. We need only look back to the condition of 30 years ago when the death rate of the country was 17.6 per 1,000 annually. It was only 12.0 in 1928 and will be appreciably lower this year. This represents an immense annual saving of lives.

Possibly one may best appreciate the significance of this change by noting the extension in the average duration of life during the interval.

In 1901, the mean length of life at birth was 47 years for males and 50 for females. In 1927, the corresponding figures were 57.9 and 61.0, a gain of about 10 years for each sex. These gains are fortunately not mere additions to the period of useless old age, but rather represent years of activity and production achieved through eliminating much premature death.

ADVANTAGES TO THE COUNTRY

It is obvious that, human life being worth what it is, its saving on an immense scale has increased the wealth of the country. For example, the gain in expectation of 10 years during the interval since the beginning of the century means an increase in the money value of a man of well over \$1,000. Under the conditions prevailing in 1901, a person of age 20 in the economic class in which the maximum annual earnings were \$2,500 would have a money value to his dependents of \$28,800. At the present time (that is, under current mortality conditions) a person at the same age would be worth \$30,200. In other words, there is a gain of \$1,400 in the value of an individual because of his longer productive lifetime. A similar gain is credited to each year of age up to age 30, and even at age 40 the greater life expectation means a gain of \$550 an individual. In other words, when we prevent disease and postpone death, we are adding large and very tangible money values to the wealth of the community. Enormous gains to individual families and consequently to the nation result when public health activities function fully and effectively. There is every reason to believe that these gains have played a very large part in bringing about a higher standard of life and a more diffused prosperity to the people of the United States. Those who live longer, less harassed by preventable disease, can work more, produce more, pay larger taxes, and play an altogether more valuable part in the life of the nation.

I do not for a moment assume that all the lives saved and all of the cases of disease prevented have been due to public health activities. Other factors have undoubtedly played their part; but no one would deny that it is to the organized health agencies of the country, whether under public or private auspices, that we owe our greatest debt. It is particularly interesting that these health agencies have performed their services at a cost so small as to be almost negligible. It has always amazed me to see how minimal the figures are which have produced results so important to the national economy.

According to recent studies in a group of 183 cities, the average expenditures for public health work were highest in the largest cities. In those with 100,000 and more, the average health department ap-

propriation, exclusive of hospital care, was about \$.62 per capita. In the cities between 30,000 and 100,000, the appropriation was \$.525, and in those between 10,000 and 30,000, only \$.47 per capita. These figures do not include the expenditures of the voluntary agencies.

In another group of 108 cities which were enrolled in the Health Conservation Contest launched by the Chamber of Commerce of the United States last year the per capita figures were somewhat higher. The average expenditure of the health departments in these cities was \$1.03. In the 10 cities of over 500,000 population, the average was \$1.15; in the 6 between 250,000 and 500,000, the average was \$1.34. The highest expenditure was in the 16 cities between 100,000 and 250,000, with an average of \$1.76 per capita. The cost of health service in the smaller cities varied from \$1.03 to \$1.22. These figures include the expenditures of the official health department, any health work of the board of education, and that of all voluntary health agencies, but do not include the cost of hospital care in any form.

Even the cities which carried off the highest awards in the contest showed extremely moderate expenditures. Thus, Milwaukee reported only \$1.31 per capita last year, including the cost of public health service by private agencies; Syracuse, N. Y., a total of \$3.05 for all expenditures; East Orange, N. J., \$1.22; White Plains, N. Y., \$2.75; and Sidney, O., \$1.21. The average cost of all types of public health service in this group of 5 leading cities was only \$1.75. In other words, about \$1.50 represents the outlay in cities that have taken their health work seriously and are achieving worthwhile results. It is clear that by and large, the municipalities of the country are running well below this figure.

The costs in our rural areas are considerably lower than in our cities. Counties whose health work has attracted attention are spending little more than \$1 per capita per annum and the general run is much less. Taken all in all, if we include all types of public health service, official and private, local as well as state and federal, the annual figure will be considerably under \$1 per capita for the people of the United States; but even if we should assume an average of \$1 per capita in order to play absolutely safe, the total for public health work would reach only a little over 120 million dollars per year for the entire country.

This sum is small indeed when we consider the number of lives at stake and their enormous money value. Obviously there is a great disproportion between the two accounts which we are balancing, namely, of outlay and of savings. That is why it is suggested that public health activities, when well conducted, are among the most de-

sirable and profitable of public investments. In many respects, these efforts are only beginning. The pitifully small amounts expended for health service in so many cities and in the rural areas of the country show how backward we are in making available to all people the benefits of present knowledge. Practice and application lag far behind what we now know very well how to do. While it is true that the general death rate has been reduced to a very low point, there are still close to 100,000 deaths a year from tuberculosis. I am confident that three-quarters of these could be postponed for shorter or longer periods. There are large areas in the country where little or nothing has as yet been done to cope with the tuberculosis problem.

When our present knowledge regarding the care of certain types of pneumonia is put into operation on a large scale, we should succeed in reducing the number of deaths from this disease by one-third to one-half. Pediatricians agree that deaths from diphtheria can be virtually eliminated and those from diarrhea reduced to one-quarter of the present number. All but 5 per cent of the remaining typhoid cases can be prevented. Safety engineers are very confident of their ability to reduce by a quarter the number of accidents in industry, in our homes, and on our highways.

The great problem still remains how best to prevent and treat the ailments of middle life, namely, heart disease, Bright's disease and cerebral hemorrhage; but even here progress is being made. Information as to the causes leading to these degenerative conditions is increasing. It is not too much to expect that a perceptible proportion of deaths can be postponed for a time at least.

For these reasons, I estimate that the expectation of life can be increased by more than 5 years provided the knowledge now available be utilized by health organizations, public and private. The expectation of life in the country as a whole can be extended to a span of at least 65 years. This is not an idle dream for it has virtually been done in far-away New Zealand. Progress will go considerably beyond this point; exactly how far, will depend upon new discoveries in preventive medicine in our laboratories and clinics.

The vital question is whether the American people are really in earnest about expanding the public health program and in proving its effectiveness. It will be necessary, of course, to strengthen the facilities of health departments, to build up more efficient organizations, train health workers better, make their tenure of office safer, pay them more adequate salaries, and develop a more professional spirit among them. This will necessitate larger expenditures. But so small is the amount spent at present that there should be no difficulty in

obtaining increased funds in a country as rich as the United States.

Our best authority, Professor Winslow of the Yale School of Public Health, has estimated that an expenditure of only \$2.50 per capita for health service will provide all of the activities of a well rounded program. Other authorities and experience attest to the soundness of this estimate. Health appropriations should, however, remain flexible. Where there are special difficulties to overcome, as in malarial regions or where special racial groups present health problems requiring additional services, the per capita figure should be higher; but taken by and large, an expenditure of \$2.50 per capita for the country as a whole, including the rural areas, will be found adequate. This moderate sum will provide all the facilities that can profitably be used at present. As additional knowledge becomes available and health departments can safely extend their operations into new fields, the amounts may be somewhat increased. At any rate, the figure given is sufficient to maintain the best current practice. A total expenditure of 30 million dollars for the public health service of the entire nation, or about 180 million dollars more than is now being spent, is all that is necessary.

I need not stress the insignificance of the amounts now expended for public health service. As a nation, we have learned how to spend money freely for things inconsequential as compared with public health. We are notorious for our large outlays for luxuries of every character. Our annual candy bill has been estimated as high as 690 million dollars; perfumes and cosmetics consume another half billion, and our tobacco bill is rapidly approaching the 2 billion dollar mark, if it has not already passed this point. In a country like ours, there should be no great difficulty in making available soon the small sum which if put into the hands of our health authorities would give them the power to reduce sickness and prevent death as far as our present knowledge permits.

I am very optimistic over the prospect of achieving this ideal. The business men of the country are already waking up to the fact that it is to their interest to further the public health campaigns. They realize that a good health record is a business asset for a city and they advertise this widely in their effort to attract industries, conventions, and the travelling public. Possibly, no more significant event has taken place in recent public health history than the entry of the Chamber of Commerce of the United States into a close alliance with the American Public Health Association. The launching of the City Health Conservation Contests is really an accomplishment of the first importance.

Already in 200 cities, local chambers of commerce are interested and are coöperating actively with their local health officers and the public to make possible improvements of all kinds in the health service. This active interest of the business men should make a profound difference in the amounts appropriated for local health service. I hope it will not be long before 500, yes even 1,000 cities, will enter the contest and make the good natured rivalry among them a national institution. There is no better way to direct the attention of the public to the importance of their health service. When this has been achieved, it will not be necessary to prove that expenditures for public health service are a sound investment. The results will be evident to all who wish to see.

Physicians per Capita

ACCORDING to a report prepared under the direction of Dr. Willard C. Rappleye, the United States has 1 physician to every 800 persons, a larger number in proportion than any other representative country in the world. Other countries come as follows: Switzerland, 1,250; Denmark, 1,430; England and Wales, 1,490; Germany, 1,560; France, 1,690; The Netherlands, 1,820; and Sweden, 2,860.

There is tremendous pressure by would-be students on all medical schools for admission, which would indicate that more facilities for medical students are needed, but the real basis for such a decision should be judged by the need of the country for physicians and the extent to which facilities at present meet that need.

There are 66 approved 4-year medical schools in this country which graduated about the same number of physicians in 1930 as the 131 schools then existing did in 1910.

Perhaps the most heartening finding is the fact that each year shows a larger number of applicants who have completed more than the minimal requirements for admission than the medical schools can accommodate. The most recent figures show that 50 per cent of the students applying for admission to medical schools have completed a full college course. Many take combined academic and medical courses which give them the bachelor's degree at the end of the first or second year of medicine. Of those graduating in 1930, 70 per cent had the bachelor's degree, compared with 24 per cent in 1920, and 15 per cent in 1910.—*United States Daily*, Mar. 16, 1931.

Differentiation of the Species of the Genus *Brucella**

I. FOREST HUDDLESON, D. V. M.

Central Brucella Station, Bacteriology Section, Michigan State Experiment Station, East Lansing, Mich.

THE differentiation of the known species or varieties of *Brucella* and the mechanism of their behavior which serves to separate one from the other continue to be one of the important problems occupying the minds of those who are engaged in studying this group of microparasites and the reactions which they elicit from the host. It is now known that there are three species in the genus: *Brucella melitensis* (Bruce), *Brucella abortus* (Bang), and *Brucella suis* (Traum). The accumulating data indicate that they invade and produce disturbances in the tissues of as many species of animals as any other known pathogenic microbe. The desirability of being able to identify them with certainty is therefore obvious.

It is imperative that a satisfactory method or methods be available to determine if a strain coming from one species of host is entirely different from a strain coming from another. It is also important to know whether each of the species of *Brucella* is confined to one particular host or may have several hosts. This is especially important from the standpoint of human infections if their source is to be established more definitely. At present it appears to be established that one species of *Brucella* is common to the goat, one to the cow, and one to the hog, but this does not imply that each is confined always to a single host. It may occasionally be found in a variety of hosts. In the past, a strain recovered from the goat was called *melitensis*, if from the cow it was called *abortus*, if from the hog it was also called *abortus*. Yet, those from the hog were isolated under aerobic conditions and considered more pathogenic for guinea pigs than the strain common to cattle.

The fact that a given strain comes from a cow, a hog or a goat is not conclusive proof that it is *abortus*, *suis* or *melitensis*. Not until hundreds of strains from different animals in different countries have

* Read before the Laboratory Section of the American Public Health Association at the Fifty-ninth Annual Meeting at Fort Worth, Tex., October 30, 1930.

been studied with respect to their individual peculiarities, if such exist, will the relationship of *Brucella* to different hosts be known.

During recent years there have been no less than 10 methods proposed for the differentiation of the species of *Brucella*. Most of these have dealt with only 2 of the species, *Br. abortus* (Bang), and *Br. melitensis* (Bruce). Most of these have been thoroughly discussed before. Recently, 2 more methods of distinguishing *abortus* from *melitensis* have been proposed. One, by Favilli,¹ is based on the difference in the viability of the two on a semi-solid culture medium, and the other, by Valenti,² on the bactericidal action of homologous serums coming from individuals who have recovered from undulant fever.

The first would appear to possess too great a degree of uncertainty; yet, cultures identified by Favilli in this manner and later sent to the writer for confirmation by other methods were found to be in agreement. The second, that of Valenti, appears to be valueless. We have not been successful in our efforts to confirm his findings. As a matter of fact, we have labored for 2 years to obtain a serum possessing bactericidal properties for *Brucella* and our efforts have been negative.

The McAlpine and Slanetz' method, based on differences in the glucose metabolism of *Brucella*, is satisfactory for identifying *Br. abortus*, but it does not with a certainty distinguish *Br. melitensis* from *Br. suis*.

The differential method which has received the greatest amount of attention is that of agglutinin adsorption. This is uniformly valuable in distinguishing *Br. melitensis* from *Br. abortus*, but the usual technic employed does not distinguish *Br. suis* from *Br. abortus*. Henry³ states that if R strains of *Br. suis* are used as antigen, this species may be distinguished from *Br. abortus*.

The value of any method for distinguishing closely related species of microorganisms lies in the ease and accuracy with which it can be employed and the consistency of results, even after the organism has undergone physical changes such as from an anaerobic to an aerobic state and variations in agglutinability. When more than one species occurs in infective material, such as blood or feces from cases of undulant fever, and milk or aborted fetuses from infected cattle, the differential method should tell us this fact, and further should separate one from the other. It should also find useful application in keeping laboratory cultures correctly identified.

There is another angle to the differentiation of strains of *Brucella* from humans alone which is assuming economic importance. This applies to those people in industries who when ill are entitled to disability compensation under the Workmen's Compensation Act if it can be

shown that the disability was acquired in the line of occupation. For example, if a worker contracts undulant fever while employed in an industry which involves the handling of animals, let us say hogs, and he seeks disability compensation, he will find that before his claim is approved, it will either be necessary for him to prove that he handled carcasses infected with *Brucella*, which will be impossible owing to the lapse of time between exposure and the onset of symptoms, or that the strain with which he is infected is the one common to hogs. In addition he will also have to produce proof that he has not been working with other animals or has not used raw products from cows. This is not a theoretical example. Several cases of this nature have already been brought up where it was necessary to bring forth evidence to prove that the disability, undulant fever, was contracted in line of duty.

It is firmly believed that the method¹⁰ discussed below, which the writer has studied for the past 4 years, possesses all of the qualifications which one would desire for differentiating organisms within a genus. It is based on the growth inhibiting or bacteriostatic action of certain dyes when introduced into a medium suitable for the growth of *Brucella*. It has been employed in studying 656 strains of *Brucella* as to species. These strains were isolated from cattle, hogs, horses, goats, fowls, and humans, and came from all parts of North America, Europe and Africa.

It has been necessary to make slight changes in the technic, not because the method was faulty but to overcome possible discrepancies which seem to have had the faculty of creeping in as the study progressed. Many criticisms have been raised concerning the accuracy of the method. Some are justifiable, and it has been necessary to study and answer those. We have learned that dyes of certain manufacturers are not suitable for this technic; also, that only beef liver infusion agar of the correct formula gives accurate results. We also know that through long exposure or the incubation of plates containing the dyes in a room where there are reducing gases present, such as a 37° C. incubator, the dyes are reduced and their bacteriostatic action is impaired. The lower the concentration of a dye or the more it is reduced, the less effect will it have in inhibiting the growth of *Brucella*.

The differentiation method has been based on the employment of such dyes as thionin and either methyl violet or basic fuchsin. Thionin in a suitable final dilution completely inhibits the growth of *Br. abortus*, but not that of *Br. melitensis* or *Br. suis*. Methyl violet or basic fuchsin in a suitable final dilution will completely inhibit the

growth of *Br. suis* for 72 hours, but only slightly reduce the growth of *Br. melitensis* or *Br. abortus*.

In using thionin, it is important that the 1 per cent aqueous stock solution be thoroughly shaken just before it is placed in the medium, because the dye does not make a very stable solution in water. This is also true of basic fuchsin. If too long a time intervenes between shaking and placing it in the medium, the final concentration will be too low, and satisfactory inhibition of growth will not be obtained. The most satisfactory final dilution for thionin is 1-30,000, and for basic fuchsin 1-25,000.

We have also sought and found a dye possessing more uniform and constant bacteriostatic action against *Br. suis* than any of those of the triphenylmethan series. This dye is formo-rhodamine hydrochloride, commonly known as pyronin. Pyronin is soluble, and when made up in a 1 per cent aqueous stock solution, is stable. The final dilution which should obtain for completely inhibiting all strains of *Br. suis* is 1-200,000. By using different final dilutions of pyronin it is quite satisfactory for separating each of the 3 species. A final dilution of 1-100,000 permits only a slight growth of *Br. melitensis*, while all strains of *Br. abortus* give a luxuriant growth at this dilution. The stock solutions of all the dyes spoken of should be prepared by sterilizing the distilled water and dye powder separately before putting them together.

TABLE I

THE SOURCE AND CLASSIFICATION OF THE SPECIES OF BRUCELLA ACCORDING TO BEHAVIOR TOWARD DYES

Source	Number of Strains	Species		
		<i>Br. melitensis</i>	<i>Br. abortus</i>	<i>Br. suis</i>
Human.....	236	73	67	96
Bovine.....	263	4	249	10
Porcine.....	55	0	0	55
Caprine.....	35	35	0	0
Equine.....	16	0	11	5
Avian.....	2	0	2	0
Unknown.....	49	21	23	5
Total	656	133	352	171

Thus far, the dye method of distinguishing the species of *Brucella* has been extended to 656 strains* isolated from man and animals in

* Since the presentation of this paper a strain of *Br. suis* has been isolated from the testicle of a dog sent to this laboratory by Drs. Case and Planz of Akron, O.

continental Europe, Great Britain, Africa, Maltese Islands and North America (Table I). The strains of *Br. melitensis* from man and the goat were, for the most part, isolated in European countries. It is of interest to note that the goat has not yielded any strains of the other 2 species of *Brucella*. The 4 bovine strains of *Br. melitensis* were isolated from cattle in the United States and Switzerland. The 67 human strains of *Br. abortus* were from cases of undulant fever in the United States, Rhodesia and north European countries such as Denmark, Germany, and Sweden. The 11 equine strains of *Br. abortus* were, with 2 exceptions, isolated from cases of fistula of the withers in horses and mares by Dr. C. P. Fitch⁵ of the University of Minnesota and Dr. Van der Hoeden⁶ of Utrecht, Holland. The 2 avian strains of *Br. abortus* were from fowls in naturally infected flocks in the State of Michigan. The 96 strains of *Br. suis* were from cases of undulant fever occurring in the United States. No cases of undulant fever in any European country have thus far yielded a culture of *Br. suis*. The bovine, porcine, and equine strains of *Br. suis* were isolated in the United States. It would appear that hogs are refractory to infection by *Br. abortus* since not a single strain from this source has come into the hands of the writer. The 49 unknown strains were sent to the laboratory without any history. Many of these were isolated several years ago and had passed through several laboratories before reaching ours.

DISCUSSION

If the method of identifying the species of *Brucella* according to their behavior toward dyes is correct, it would seem that one can no longer doubt that *Br. abortus* is one of the causes of undulant fever in America and north European countries. This method substantiates the epidemiological data collected by students of the disease here and abroad.

The comparative pathogenicity of *Br. abortus* and *Br. suis* for man has been based largely on the number of successful recoveries of each in blood cultures. It is a well known fact that numerous cultures have been taken in cases of the disease with negative results. It has also been demonstrated that *Br. suis* can be obtained in culture from the blood with a greater percentage of success than can *Br. abortus*. Therefore, it is perfectly evident that at present one cannot say that *Br. suis* is the predominating species in undulant fever in America just because a greater number of isolations have been obtained. If *Br. abortus* is as pathogenic for man as the epidemiological and laboratory findings indicate, there is still to be answered the important question which has been raised many times: Why is the number of cases of

undulant fever due to *Br. abortus* so out of proportion to the number of individuals that have been exposed to infective material?

It is a well known fact that, of the thousands who take *Br. abortus* into their bodies when they consume infective raw milk or cream, a very small proportion develop undulant fever. The failure of many to become infected may be attributed to a native immunity to *Brucella*. Another hypothesis that has been advanced for the low incidence of infection as compared with the numerous exposures is gradually becoming a reality. Favilli⁷ first offered the suggestion that there might be a wide difference in the virulence of strains of *Br. abortus* and that possibly only a certain strain was pathogenic for man. Meyer and Eddie⁸ also made the same suggestion based on their difference in pathogenicity for monkeys.

We have observed that strains of *Br. abortus* differ markedly in their ability to reduce basic fuchsin in beef liver agar. Those that have been studied appear to divide themselves into 2 groups: one, when grown on plates of the dye medium for 72 hours, produces a zone of complete decolorization, which extends outward and around the growth to a distance of 5 to 15 mm.; the other, grown for the same length of time, produces only a slight decolorization. This difference in dye reducing ability is true of newly isolated CO₂ anaerobic strains as well as older aerobic ones. It has also been observed that those strains which decolorize the dye slightly rarely, if ever, produce the abundant growth that is produced by the intensely decolorizing ones. The interesting feature about the 2 groups is that those strains which are not active reducers of basic fuchsin appear to come from humans and cattle, while those that completely reduce the dye come only from cattle. About 80 per cent of the strains from cattle that have been studied belong to the latter group.

One of the problems that has interested us in connection with the study of the behavior of *Brucella* toward dyes and which we have spent considerable time in trying to solve, is the nature of the bacteriostatic reaction. Our data (to be presented in detail later) show that *Brucella* possesses a very active reducing system which operates on the food in the medium to make it available for the metabolism of the cell. The activity of the reducing system varies with the species of *Brucella*. When these particular dyes are added to the medium, they combine with the food, thus preventing or retarding its reduction, and prevent or retard the natural metabolism of the cell. In order for *Brucella* to grow, its reducing system must affect one or more of the dyes. *Br. suis* possesses a very actively reducing system for thionin, but not for fuchsin or pyronin. *Br. abortus* is able to reduce fuchsin and pyronin,

but not thionin in certain concentrations. *Br. melitensis* can reduce each of the dyes in question. Its reducing activity, however, is lower for pyronin than is that of *Br. abortus*. If one artificially maintains the dyes in a reduced state in the medium, there will be no inhibition of the growth of any *Brucella*.

Besides the identification of the species of *Brucella*, the dye method, combined with the determination of the activity of H_2S metabolism, plays an important rôle in separating two species when accidentally mixed or when they occur together in a single blood culture from a case of undulant fever. Dr. Borts, of the Iowa State Board of Health Laboratories, has twice separated from a blood culture *Br. abortus* and *Br. suis* and once *Br. abortus* and *Br. melitensis* by use of the dye method.

They are also useful in separating *Brucella* from bacteria of another genus that appear like *Brucella* in their morphological and cultural characteristics and cross agglutinability. One particular organism which the writer has in mind, and which could easily be confused with *Br. suis*, is *Pfeifferella mallei*. The natural host of this organism is the horse. So also is *Br. suis* sometimes found in the horse. The lesions produced in the guinea pig by both organisms through subcutaneous or intraperitoneal inoculation are not entirely unlike in character. Both attack the same organs, producing large necrotic abscesses, and cause abscess formation of the joints of the extremities. *P. mallei* is agglutinated by serum prepared against *Br. suis*, and *Br. suis* is agglutinated by a *P. mallei* antiserum. The reducing activity of *P. mallei* for dyes differs from that of *Br. suis* in that it gives a luxuriant growth on a medium in the presence of either thionin, basic fuchsin or pyronin. *P. mallei* is also a very active H_2S producer. This gas is produced in large amounts over a period of 10 to 15 days' incubation as determined by lead acetate paper. *Br. suis* produces very little H_2S after the 4th day of incubation. Cultures of supposed *Brucella* or *P. mallei* from horses should be examined very carefully by laboratory methods in order to avoid an erroneous classification which later might be disastrous.

The dyes which inhibit the growth of *Brucella* are now being found suitable as therapeutic agents for the successful treatment of undulant fever. Leavell, Poston and Amoss⁹ have found that the daily oral administration of small doses of the dyes brings about a complete recovery in chronic or resistant cases. Thionin is administered when *Br. abortus* is involved and methyl violet when *Br. suis* is the infecting species.

Pyronin should prove even of more value as a therapeutic agent

than the two dyes just mentioned because in low dilutions it is effective against all three species, and, if given slowly, it may be injected intravenously in a 1 per cent solution without harmful effects. Monkeys easily tolerate from 10 to 20 c.c. by the intravenous route.

SUMMARY

A total of 656 strains of *Brucella* from Europe and North America have been studied in their growth behavior toward aniline dyes in a suitable medium.

It has been found that these strains divide themselves into 3 groups or species according to the growth inhibiting action of thionin in a final dilution of 1–30,000, and pyronin in a final dilution of 1–200,000 in beef liver infusion agar at a pH of 6.6.

Of the total number, 133 have been classified as *Br. melitensis* (Bruce), 352 as *Br. abortus* (Bang), and 172 as *Br. suis* (Traum). *Br. melitensis* grows on both the thionin and pyronin dye medium, while *Br. abortus* grows only on the one containing pyronin and *Br. suis* only on the one containing thionin.

The strains of *Br. abortus* may be divided into 2 classes: those which completely reduce basic fuchsin (final dilution 1–25,000 in beef liver infusion agar), and those which slightly reduce this dye. It appears, on the basis of isolated cultures, that the latter class is the one that is pathogenic for man.

When more than one species of *Brucella* occurs in blood culture or other infective material, the dye method and H_2S metabolism determination will separate and identify each of the species.

The growth inhibiting action of these dyes, especially pyronin, offers possibilities in the therapeutics of undulant fever in man and *Brucella* infections in animals.

Agglutinins for *Br. abortus* in the Blood and Milk of Cows*

Use of the Agglutination Reaction in the Control of Certified Milk

JOHN F. NORTON, PH. D., F. A. P. H. A., AND L. R. PLESS, D. V. M.

Department of Health, Detroit, Mich.

THE American Association of Medical Milk Commissions has in its regulations the statement that "No cow known or suspected to be diseased shall be permitted to remain in the milking herd." Acting under this regulation, the Wayne County Medical Milk Commission agreed to a tentative procedure in an effort to exclude from production of certified milk all animals which were to any degree likely to convey the organisms of undulant fever to the consumer.

The blood agglutination test with a *Br. abortus* antigen has been used for some time as a means of excluding possibly dangerous animals. The presence of agglutinins in the blood cannot be regarded as satisfactory evidence of active infection. While exclusion of producing cows on the basis of this test would certainly be a safe procedure, it would seem to be entirely too rigid a criterion for practical purposes. On the other hand, the actual isolation of bacteria of the *Br. abortus* group from the milk of each animal is impractical from the standpoint of a control laboratory, not only because of the laborious and time consuming technical procedure but also because negative findings would be of little value. The procedure agreed upon as worth a trial was to exclude from milk production those animals in which both the blood serum and the milk serum contained agglutinins for *Br. abortus*.

In order to obtain some data in regard to this requirement, during the past year both blood and milk reaction tests have been made on all cows producing certified milk on the five farms supplying Detroit.† To obtain more data on animals giving a positive blood test, 250 such cows on Farm A are included, although the milk is not part of the certified supply.

* Read before the Laboratory Section of the American Public Health Association at the Fifty-ninth Annual Meeting at Fort Worth, Tex., October 30, 1930.

† The laboratory work was done by James G. Thomas and Marguerite Novy.

The samples of blood were collected, allowed to clot and the serum removed in the usual manner. The milk samples were collected from each quarter of the udder separately, rennet added and the serum removed after transportation to the laboratory. At least 3 blood and 2 milk tests were made on each animal. The agglutination test was performed with Huddleson's antigen and the technic followed was that of Huddleson's rapid method, using the following serum dilutions: 1-25, 1-50, 1-100, 1-200, and 1-500. As a tentative procedure, serums showing agglutination in a 1-100 dilution or higher are recorded as positive, those showing agglutination in 1-25 or 1-50 are recorded as positive-negative and those showing no agglutination as negative.

The results of agglutination tests for each of the five farms are given in Table I. The practice at Farm A has already been referred to. At Farm B, Huddleson's non-agglutinating vaccine was being used during the period of the tests. The cows on Farm C had been vaccinated with a non-virulent agglutinating vaccine from 6 to 18 months before the samples were collected. On Farm E many more blood reactors were obtained than are shown in the table, but these animals were immediately disposed of and were not available for milk tests.

TABLE I

AGGLUTINATION OF BR. ABORTUS BY BLOOD AND MILK SERUMS

Farm A		Farm B		Farm C		Farm D		Farm E	
Blood	Milk	Blood	Milk	Blood	Milk	Blood	Milk	Blood	Milk
	+ 36		+ 3		+ 10		+ 2		+ 0
+ 71	± 6	+ 9	± 1	+ 43	± 3	+ 9	± 0	+ 4	± 0
	- 29		- 5		- 30		- 7		- 4
	+ 0		+ 0		+ 0		+ 1		+ 1
± 43	± 0	± 4	± 1	± 43	± 0	± 14	± 1	± 11	± 1
	- 43		- 3		- 43		- 12		- 9
	+ 0		+ 1		+ 0		+ 0		+ 0
- 193	± 0	- 81	± 0	- 32	± 0	- 26	± 0	- 64	± 1
	- 193		- 80		- 32		- 26		- 63

Six hundred and forty-seven cows were examined. Of these, 396 or 61.2 per cent were non-reactors to the blood serum test; 115 or 17.8 per cent gave an agglutination in serum dilutions of 1-25 or 1-50; 136 or 21.0 per cent agglutinated the antigen in a dilution of 1-100 or higher; 579 or 89.5 per cent gave no reaction in the milk serum at any time from any quarter of the udder. The milk serum from 14 or 2.2 per cent agglutinated the antigen in a dilution of 1-25 or 1-50 in one or more quarters at some time; 54 or 8.3 per cent showed agglutination in dilutions of 1-100 or higher. Since these gross figures are of relatively little importance, all the data have been separated so as to show

the number of positive or negative bloods giving positive or negative milk reactions. In Table II the results are combined and summarized. Of the cows showing no blood reaction 99.5 per cent gave no milk reaction; 95.7 per cent of the reactors in low dilutions (1-25 or 1-50) gave negative milk tests. For practical purposes it would appear that if a blood serum agglutination test is negative or positive with a serum dilution less than 1-100, the chances are small of obtaining a positive milk reaction. The exact significance, however, must depend upon ability to isolate *Br. abortus* from the milk.

TABLE II
SUMMARY OF AGGLUTINATION TESTS
647 Cows

		<i>Blood</i>								
		+			±			—		
Number		136			115			396		
Per cent		21.0			17.8			61.2		
		<i>Milk</i>								
		+			±			—		
Number		51	10	75	2	3	110	1	1	394
Per cent		37.5	7.3	55.2	1.7	2.6	95.7	0.25	0.25	99.5

Of the 136 blood reactors, 55.2 per cent gave no milk reaction; 7.3 per cent gave a reaction only in dilutions of 1-25 or 1-50; while the remaining 37.5 per cent were distinctively positive. Here also the significance of the negative milk reaction must be checked by further bacteriological data.

It is essential that the quarters of the udder be tested separately, since dilution might mask a positive test in one quarter. This possibility is indicated by the following data: the results of 100 laboratory tests showing at least 1 positive reaction in milk from the 4 quarters were picked at random. Of these, 26 were positive in 1 quarter only, 23 in 2 quarters, 17 in 3 quarters and 34 in all 4 quarters.

It is particularly desirable that all animals be tested after freshening (15 to 30 days). There were many instances where a negative reactor changed to a positive within a month after calving. Blood and milk serum tests during gestation are of relatively little value. A careful history of each animal is essential to proper interpretation of the reactions obtained in the laboratory.

That a positive blood test alone does not indicate active abortus infection is shown by the fact that many cows in this group have never aborted. Records over a period of several years were available on one of the farms.

Another fact noted was the rapid change in the milk serum agglutinin content in some animals. The antibodies may disappear completely in a few weeks, or a negative animal may become positive in the same time.

The following procedure is recommended as a practical control measure in connection with the production of certified milk.

1. A blood serum agglutination test with a *Br. abortus* antigen is made (a) on all producing cows twice a year, and (b) on all cows between the 15th and 30th day after freshening.

2. Samples of milk from each quarter separately are taken from all animals giving a positive reaction in blood serum dilutions of 1-100 or higher.

3. Animals showing any agglutinins in the milk serum from any quarter of the udder are immediately excluded from the producing herd.

4. The excluded animals are re-tested one month later, and if still positive are isolated from the certified barns.

NOTE: This work was done in the Detroit Department of Health. We are indebted to Michigan State College for some of the data here presented and to the several farms for their active coöperation.

Thus Saith the Lord

THE effort to promote and preserve public health by the pronouncement of edicts by or under authority of sovereign power is of ancient origin.

The ten commands of God respecting moral and civil obligations, written on tablets of stone and given by Moses to the children of Israel, are not older in time than that code of sanitary regulations for the preservation of the health and safety of the people, minute and particular in every detail, wherein God, through Moses, commanded his people to observe frequent purifications and cleansings; to isolate those suffering from communicable diseases; to disinfect houses where the plague had prevailed; to destroy infected articles; to avoid the use of unwholesome foods; and to protect the roofs of their houses by battlements, "that thou bring not blood upon thine house if any man fall from thence."—

Public Health Control of Infectious Abortion in Certified Milk*

K. F. MEYER, PH. D.

George Williams Hooper Foundation for Medical Research, University of California, San Francisco, Calif.

HISTORICALLY the control of the *Brucella* infections as applied to certified dairies was initiated and subjected to careful tests by a series of developments which have been recognized during the past 15 years.

It has always been the opinion of those interested in the certified milk problems that for practical purposes this article of food as produced under the regulations for certification was a safe raw milk. However, it must be emphasized, and the fact credited to the sincerity of the certified milk movement, that when suggestions began to be offered and the efficiency of the control as well as the safety of the product questioned, groups of workers began to investigate the foundations on which the whole principle was based.

The Commissions, cognizant of their responsibility, always felt that within certain limitations a dependable safeguard had been erected by a rigid system of dairy hygiene. One weak link in the chain, emanating from the cattle themselves, existed in the diseases to which man is heir. At first tuberculosis played a leading rôle, then the streptococcic infections, and finally, through the observations of Fleischner and Meyer in 1915, the significance of the infectious abortion in certified herds was recognized. The original observation that certified milk may harbor the representatives of the *Brucella* group was made as early as August, 1915. Strain No. 80, now well known and extensively used for serologic tests, and in recent years designated as a *Brucella abortus suis*, was isolated at that time.

No effort was spared by the two workers mentioned to secure clinical or epidemiological evidence relative to the infectiousness of the certified milk consumed during 1915 and 1916. Since these inquiries were entirely negative and the trend of the prevailing discussion clearly indicated the lack of sufficient proof to incriminate the bacterium as

* Read before the Laboratory Section of the American Public Health Association at the Fifty-ninth Annual Meeting at Fort Worth, Tex., October 30, 1930.

harmful to man, the Milk Commissions decided to take an expectant attitude. However, the feeling of the members was clearly expressed in the conclusions which Fleischner and Meyer presented before the 68th session of the American Medical Association in 1917. They said: (1) For practical purposes *Brucella abortus* is always present in certified milk produced in the San Francisco Bay region; (2) it is of greatest importance to study the abortus problem from every angle to be absolutely certain of its bearing on the health of infants.

A study was made of 75 infants fed for from 1 to 12 months on a raw milk containing a large number of *Bacillus abortus*, and later supplemented by a group of 200 children in the age class 0 to 5 (unpublished data). Their serums were subjected to agglutination tests with negative results. With 2 exceptions, negative cutaneous allergic tests were also recorded. The 2 positive tests were in children suffering from bone tuberculosis of long standing and, in view of available knowledge at that time, were interpreted as nonspecific co-reactions due to general sensitization with tuberculo-protein.

Fleischner and Meyer introduced the intradermal tests not only in the diagnosis of animal infections in order to distinguish tuberculous infections from those caused by the *Brucella* organism, but also as an aid in the recognition of human infections due to the latter bacteria. Reports in the Italian and French literature at that time indicated that the customary serologic tests might be inconclusive in chronic or mild subclinical infections.

Since a diligent search over 2 years for acute *Brucella* infections in children had failed to reveal such conditions, it was reasonable to suspect that the disease existed, if at all, in the subclinical or immune stage and could probably be recognized by means of allergic tests. Unfortunately two important facts were not considered: (1) The past history of undulant fever was not carefully analyzed; the brilliant treatises of Hughes,¹ Cantaloube² and Eyre³ were superficially read and consequently it was not realized that the age group 0 to 5 in countries north of the 45th latitude possesses a very high immunity against this infection; (2) the nature of the "abortion reaction" was incompletely understood, consequently the evidence adduced from the clinical, serological and allergic studies was considered suggestive that *Brucella abortus* (bovinus) is non-pathogenic for infants and children.

Irrespective of the negative findings in 1917 and 1918 it was deemed important to approach the solution of the question in the mind of the Milk Commissions: "Is the *Bacillus abortus* discharged in the milk of dairy cattle infectious for man?" by various investigative routes. A few of the contemplated studies were completed. How-

ever, it was of considerable significance that in the course of a comparative analysis of a series of cultures, a *Brucella* strain originally isolated from a human patient in Austria was found to behave, culturally and serologically, like a *Br. abortus bovis*. Furthermore, feeding experiments on monkeys left no doubt that the *Brucella* organisms isolated from cow's milk, when administered by mouth in sufficiently large dosage, are pathogenic for these animals.

In 1919 the entire evidence was carefully analyzed, and it was pointed out that future bacteriological work might reveal a strain of *Br. abortus* which, in relation to its invasive properties, approached *Br. melitensis* more closely than those studied. A search for such a strain or strains was planned, but one member of the San Francisco Milk Commission (K. F. M.) was obliged to devote his entire attention to another problem of food sanitation and discontinued his studies on the *Brucella* group for 7 years. The San Francisco Milk Commission continued to take a great interest in the reports which gradually established a causal relationship between bovine abortion disease and undulant fever in man.*

In 1921 Bevan¹ reported the development of undulant fever in a number of human beings in Rhodesia, none of whom had consumed goat's milk. The evidence pointing to cattle as a source of infection was circumstantial, although subsequent tests by Orpen² showed these cases to be caused by the abortus type of the *Brucella*. Promptly, from widely separated parts of the world and the United States, cases were reported which were in all probability caused by organisms from bovine sources. By the end of 1925 the observations of Keefer,³ Evans,⁴ Carpenter,⁵ Huddleson,¹⁰ and others strongly indicated that the *Br. abortus* infections may assume an important public health aspect. The San Francisco Milk Commission was particularly alarmed by a case reported by Dickson.⁴†

No cases of undulant fever were recognized in California during 1926. However, the American Association of Medical Milk Commissions invited Drs. George H. Hart and Earle M. Dobbs of the University of California to discuss at the Twentieth Annual Conference at Dallas, Tex., April 20, 1926, the relation of *B. abortus* to public health. The authors concluded that the few cases of undulant fever reported in various parts of the world, including 12 in the United States which

* During the most critical years the San Francisco Commission seriously missed the counsel of Dr. E. C. Fleischner, whose untimely death doubtless deferred the organization of drastic control measures until 1927.

† A woman who had not been in contact either with goats or cattle was advised to consume 5 to 6 glasses of milk daily. She developed undulant fever with a positive agglutination test in a dilution of 1:500. Epidemiological studies showed that part of the milk consumed had been raw and abortus organisms were isolated from 2 cows in the dairy.

could not be traced to goats, were, in the light of the work done by well known investigators, cases of bovine origin.

The views expressed were fully shared by the Milk Commissions of the State of California and forcibly expressed at a meeting of the State Association in December, 1926. In fact, plans were discussed with Dr. C. M. Haring and members of the Division of Veterinary Science of the College of Agriculture, University of California, to apply to the certified dairies the system of control of Bang's disease so effectively administered since 1924 in a herd at a State Hospital.*

A number of developments during the first quarter of 1927 crystallized into a definite plan of procedure. In January, 1927, the Hooper Foundation was requested to examine a specimen of blood serum from a patient living at Morenci, Ariz. The serological study indicated an infection with *Br. melitensis*. Two cultures subsequently forwarded confirmed the diagnosis. In March another specimen of serum was forwarded from Los Angeles. The absorption test suggested an infection with the abortus variety. In the course of the next 8 weeks, 6 other specimens of blood serum of a series of 17 gave definite agglutination reactions with the abortus variety. These findings aroused tremendous interest, particularly since all the patients denied any contact with goats or goats' milk products. On the other hand it was claimed that all had consumed during the past 6 or 8 months large amounts of raw cows' milk. An attempt was made to determine the sources of the milk and the same number of dairies as there were patients were found to have furnished it.

The Commissions promptly recognized the significance of these scattered cases and, although no infections had been connected with the certified milk supply of the large cities, a serological survey covering the extent of brucellosis of the dairies was ordered. The tests were made in April, 1927, and approximately 20 per cent of the milch cows were thus found to give positive reactions indicative of an active past or latent but stationary herd infection. Market milk supplies of two dairies were tested on guinea pigs. They demonstrated the presence of *Br. abortus* in both specimens. The owners were instructed to proceed under the direction of the Division of Veterinary Science with the control of the infection by the segregation method.

Due consideration was given to these recommendations in the draft of the revised requirements of the California State Association of Certified Milk Commissions (Alameda, Los Angeles and San Francisco Counties) adopted late in 1927 and put in effect January, 1928.

* For details the reader is referred to *Circular 44*, California Agricultural Extension Service (Fred M. Hayes, Bang's Disease), University of California, 1930, pp. 17-24.

Paragraph 42 of the requirements which specify the control of Bang's disease reads:

After July 1, 1930, only animals free from *Brucella abortus* infections shall be permitted in a certified dairy, or to come in contact with any animal in a certified herd. The agglutination test of the blood serum shall be used for the determination of latent infections or carriers. The tests are only recognized by the Commissions when conducted by or under the supervision of the Commission's veterinarian. No animal shall be added to a certified herd until it has been tested for abortion disease by the Commission's veterinarian.*

The dairies complied with the requirements, but since the Commission for economic reasons desired to control the disease gradually over a period of a year and a half, several hundred reacting animals were removed when opportunities occurred to dispose of them. This prevented replacement by purchase and thus obviated conditions which in the long run would have jeopardized seriously the ultimate eradication of the infection. Irrespective of the defects inherent in a system of segregation in the dairy the number of reactors in the 4 certified herds was reduced as follows in 1928:

TABLE I

Herd No.	Av. No. Animals	Per cent	Periods
1	323	7.7	Jan., 1928
"	"	0.6	Dec., 1928
2	430	17.9	May, 1928
"	"	0.5	Dec., 1928
3	218	6.0	Jan., 1928
"	"	0.5	Dec., 1928
4	82	2.2	Jan., 1928
"	"	1.3*	Dec., 1928

* No effort made to remove reactors promptly.

The preliminary control work favored a prompt response and by May, 1928, the serum tests revealed 2 herds without a single reactor while the 2 others showed 1 and 2 respectively. The eradivative measures were very strict and the reactors were promptly removed from the farms. The histories of the herds for the year 1929 and the first half of 1930 are shown in Table II.

In order to verify the effectiveness of the control measures and as an additional check on the serum tests, the Division of Veterinary Science began a procedure which must be considered an important step toward the assurance of the Commissions and the consumer that certified milk is free from *Br. abortus*. This test, previously used in other states to recognize *Brucella* shedders in vaccinated herds, was intro-

* Repeated tests are now required.

TABLE II

Herd	Dates of tests and percentage of reactors in total number of animals tested							
	February 1929	March 1929	April 1929	May 1929	June 1929	August 1929	October 1929	November 1929

duced into the routine tests of the dairies in the San Francisco Bay region. Since October, 1929, and every 30 to 60 days thereafter samples of certified market milk from each dairy have been collected and guinea pigs injected with the cream and sediment. The results have been negative with 1 exception.

It will be noted in Table II that Herd 3 suddenly revealed, in May, 1930, 1, and in June, 2 reactors. The blood serum of the cow detected in May, 1930, agglutinated in a dilution of 1:3,200; her milk serum reacted with the abortus antigen in a dilution of 1:100. She was one of the milking string of 50 cows. A sample of milk of this dairy bought in the open market was tested on guinea pigs. Typical abortus infections resulted. Additional guinea pigs were injected with market milk samples after removal of the cow. They revealed no lesions. The udder secretion of the reactor cow contained abortus organisms.

The actual dilution of this infected milk in the positive market sample is not known. From a practical point of view this is not necessary since the observation conclusively demonstrates the contamination of the milk supply by one animal. Absolute freedom from reactors is therefore an indispensable prerequisite for a certified milk.

In this connection it may be of interest to consider the sources of infection of the animals in Herd 3. A canal separates the farm from one which maintains a large dairy herd of which about 300 are infected with Bang's disease. The irrigation ditches for both farms lead from this canal and the possibility exists that water is the carrier. Large flocks of crows inhabit this territory. Frequently these birds feed upon aborted fetuses and placentas on the one farm and fly across the canal to the barn yard and feed racks of the certified dairy. There may be other sources of infection but either of the above may serve as the carrier. It is obvious that a certified dairy in the vicinity of a large reservoir of infection requires continuous and vigilant supervision.

The magnitude of the problems involved in the eradication of brucellosis is apparent when one considers the work and results obtained by the Los Angeles Milk Commission. Control measures were instituted in 1927. An initial survey in July of 3,071 animals revealed 38.2 per cent reactors distributed through 5 dairy herds. A system of segregation and replacement by purchase was instituted. Progress in the control program was at first quite rapid, and by 1929 the tests revealed approximately 1.7 per cent reactors. Only those who are familiar with the size of dairy herds in Southern California will appreciate that the producers of certified milk willingly assume a gigantic task in replacing in a very short time as many as 400 reactors on 1 farm. One should therefore not underestimate the disorganization and expense (cost of 16,000 serum tests in 6 months) entailed in the eradication of Bang's disease from large dairies. Formerly self-containing units entirely dependent on replacement by raising were forced to

TABLE III

Serum Test	Date	Per cent Reactors
First	July-August, 1927	38.2
Second	November-December, 1927	10.7
Third	February-March, 1928	5.4
Fourth	August-September, 1928	5.4
Fifth	December, 1928-January, 1929	2.8
Sixth	April-May, 1929	1.7

search the country for suitable milch cows free from disease. That they succeeded in some measure is illustrated by the data (Table III) which the President, Dr. Fitch C. E. Mattison, presented at the An-

nual Conference of the American Association of Medical Milk Commissions at Montreal, 1929.

Late in 1929 the Commission organized and now supports with the aid of the producers a well equipped laboratory entirely devoted to the medical and veterinary supervision of the products of the certified dairies in the Los Angeles district. Systematically the cows are tested at 30- to 60-day intervals. Market samples of each dairy are collected every week and guinea pigs injected with the cream and sediment of a specimen of 80 c.c. The work is conducted by Drs. C. W. Bonyng and J. P. Bushong.

The low incidence of reactors was unfortunately not maintained, largely because of the replacements by purchase. Although the herds were invariably stocked with negative reactors, animals with latent infections were probably introduced and the incidence of reactors rose from approximately 1 to 6.4 per cent. Consequently it was not surprising to encounter guinea pigs with definite abortus lesions. In general the anatomical, cultural, and serological findings were indicative of infections with few organisms, and the presence of abortus bacilli was irregular.

The analysis of the information thus far collected by the two Commissions suggests the following conclusions: (1) The eradication of Bang's disease in large dairies dependent for replacement of the reactors by purchase is a slow process; (2) the mixed market milk from such herds continues to harbor abortus bacilli in small numbers until the percentage of reactors is below 1 per cent; (3) although epidemiological investigations during the past 6 months, and serum tests on children who consumed this milk have failed to reveal undulant fever infections, it is the earnest desire of the Commissions to press vigorously the control measures until the number of the reactors is reduced to zero; (4) by comparison it is evident that herds in which no attempts are made to eradicate Bang's disease, and the percentage of reactors is large, unquestionably furnish a milk heavily infected with abortus bacteria; (5) certified herds which are subject to reinfection from neighboring herds and those which depend upon replacements by purchase must be subjected indefinitely to serum tests at intervals of from 30 to 40 days; (6) the Commissions should certify only milk which is free from abortus bacteria as shown by repeated guinea pig tests, preferably made at weekly intervals. Only cows known to be non-reactors to the agglutination tests furnish such milk.

Independent of the pioneering work done on the Pacific, the American Association of Medical Milk Commissions has discussed the public health aspect of Bang's disease at every annual meeting since 1925.

As a national organization devoted to the production of the highest quality milk, a great responsibility had to be assumed in deciding a matter which presented many controversial aspects. Two facts invariably deferred immediate action to compel the producers of certified milk to eradicate Bang's disease from their herds:

First, epidemiological studies had shown that although the majority of cases of undulant fever gave a history of having consumed raw milk, there remained a fairly large percentage in which other contacts with the *Brucella* organism were evident. In certain sections of this vast country, abortus fever is an occupational and not merely a milk-borne disease. The careful investigations of Kristensen and Holm definitely indicate that one-third of the 500 cases investigated in Denmark may be attributed to milk.

Second, it remains a noteworthy fact that great reluctance continues to be expressed in offering final conclusions and a solution for this complex problem. As late as 1929, Theobald Smith¹⁴ made the significant statement: "As to active measures against undulant fever, if it should be made fairly clear that the bovine race of *Br. abortus* is the real source of the other races then the time would be ripe for an active campaign against it."

It was therefore felt that adequate safeguards either in the form of pasteurization or elimination of the *Brucella* carrier in the herd must be instituted as soon as the actual rôle played by milk is definitely established. The papers read by Drs. I. F. Huddleson and J. G. McAlpine in 1928 before the Twenty-second Annual Conference at Minneapolis and the review presented by Dr. J. G. Hardenbergh before the Metropolitan Certified Milk Producers Inc. in February, 1928, amply testify to the trend of the deliberations. Furthermore, the presidential address read at the 1929 meeting of the American Association of Medical Milk Commissions at Montreal emphasizes the earnestness with which the entire problem was approached.

The speed with which the eradication of Bang's disease is to be undertaken was left largely to the discretion of the County Milk Commissions. However, a circular inquiry made during September, 1929, by the secretary of the association disclosed the fact that plans to eradicate Bang's disease in certified dairies all over the country were well under way. Some of the results reported were: 102 farms answered; 85 tested or tests under way; farms supplying milk from 100 per cent negative animals: 42, or 49 per cent; from 75-90 per cent negative animals: 15, or 17 per cent; from 66 per cent negative animals: 6, or 8 per cent; from less than 66 per cent, or not stated: 22, or 26 per cent.

It has been estimated that by the middle of 1930 approximately 80 per cent of the certified dairies were actively engaged in a program of eradication of Bang's disease. The procedures in vogue were blood tests every 60 to 90 days, segregation, disposal of reactors or suspects, cleanliness and disinfection, replacements by animals which gave negative tests. To the astonishment of everybody concerned, it was noted that 6 farms used vaccines. In one instance the producer tried to determine the degree of the herd infection by serum tests. Of 50 animals reported, 28 reacted positively, 20 suspiciously and only 2 were negative. In order to accelerate the control of *Brucella* infections in certified dairies the National Association adopted, June, 1930, the following rules pertaining to the control of *Brucella* infections:

It is required that elimination of Bang's abortion disease be actively prosecuted to the end that this disease be eradicated as early as possible from certified herds.

(a) No animal shall be used in the production of certified milk that shows positive evidence of infection with *Brucella* organisms.

(b) Herds shall be under the supervision of such agencies as shall be acceptable to the State Livestock Sanitary authorities and to the local Milk Commission.

As already mentioned the execution of the methods and standards is left to the County Milk Commissions. The National Association will try to collect reliable data regarding the progress of the control work and will doubtless publish from time to time the results or failures noted.

From the foregoing review of the trend of the various Milk Commissions toward the elimination of Bang's disease in the herds under their supervision it is evident that the entire problem has been approached with the facilities made available by those who have been engaged in this work for the past 5 years. Probably for many of the certified dairies the principles are not practical and the Commission will have to work out special procedures. For example, the important problem of the most economic disposal of the reactors requires some unified plan of action. To offer these animals for sale and thus to disperse them all over the country presents a great menace to the dairy industry.

In most cases the reacting cows represent valuable breeders which are eagerly sought by unscrupulous dealers to build up new herds. In order to prevent such dangerous practices the Commissions should insist that the reactors be segregated on separate farms far removed from the certified herd. The milk of these animals must be pasteurized, while the isolated herd may be used for the rearing of heifers free from abortion disease.*

* For details see *Circular 33*, California Agricultural Extension Service, College of Agriculture, University of California, 1929.

One is frequently asked: What results can be expected if the program of eradication is completely carried out? Since a great many factors in the epizootology of brucellosis and the epidemiology of undulant fever in man are still unknown, any statement would probably be contradicted by new facts discovered in the future. However, two possibilities should be considered:

First—The control and eradication measures now practised in many communities on a purely voluntary basis, although quite successful, may require legal enforcement. As an alternative, the co-operative plan known as the "Pennsylvania plan" may be adopted. Isolated farms free from Bang's disease contain highly susceptible animals, and when surrounded by infected herds are subject to catastrophic losses. Against such a possibility the certified dairy must protect itself by continuous serum tests at 30-day intervals. Until the dairy industry as a whole embarks on a plan to control Bang's disease, the position of the Brucella-free dairy will remain precarious and the efforts of the Commissions thus be nullified.

Second—Experience with regard to the elimination of Bang's disease by the segregation or eradication methods in certified dairies is based largely on the observations of livestock sanitarians throughout the United States. In California neither energy nor expense has been spared. With an unbiased mind the task has been undertaken and it is anticipated that it will be carried out successfully. The next 12 months will show if the milk of certified dairies can be kept free from Brucella organisms. Every effort will be made to keep the clean herds free from the disease. If the desired goal cannot be reached, then public health interests may remain assured that the Milk Commissions will be the first to introduce pasteurization of the milk under their care. In anticipation of such a possibility the American Association of Medical Milk Commissions appointed, in 1929, a Committee on Scientific Research, which will concern itself with approving, advising or actually directing certain research projects of importance to the dairy industry.

One of the principal projects, aside from the Brucella infections, which has occupied the attention of the committee deals with the study of the physical, chemical, nutritive, and bacteriological characters of milk as influenced by age, heat, cold, aeration, or exposure to various gases, radiation, contact with metals, etc. The necessity for such fundamental studies was admirably detailed by Dr. M. J. Rosenau at the Detroit Conference of the Milk Commissions. These studies, which would extend over a term of years, would then be followed by the second phase of investigation: a comparative study of the various

methods of commercial pasteurization and commercial pasteurizing machinery. Since the Medical Milk Commissions promote the production of milk of highest quality the pasteurization cannot be solely viewed as a safety factor, but the effect of heat on the nutritive factors in milk and many other conditions must be more definitely understood than hitherto.

Nobody will question the great benefits derived from pasteurization. However, the sanitarian and the consuming public are entitled to expect that the methods and supervisory control will be superior to those now generally in vogue should pasteurization of certified milk be undertaken.

With the knowledge now available the Commissions are left in a quandary as to the kind of equipment to be used in an individual or co-operative plant, the time and temperature, the extent of the supervision, and other matters. In fact, it would be very difficult at present to draft a set of regulations. Years of fundamental research are required. It is therefore hoped that in the meantime Bang's disease may have been banished from the certified dairies and that the problems which face the Commissions may be less serious.

Further Studies on *Brucella abortus* in Certified Milk*

D. E. HASLEY

*Department of Bacteriology and Clinical Diagnosis, Detroit College of Medicine
and Surgery, Detroit, Mich.*

IN a previous study of the certified milk sold in the city of Detroit it was found possible to detect, by plating methods, *Br. abortus* in the milk from 3 of 5 herds studied.¹ Two hundred and thirty samples of certified milk were collected and plated from December, 1928, to September, 1929, in an attempt to isolate members of the *Brucella* group. These samples were taken from bottles ready for delivery and were plated when at about the same age as milk reaching the consumer—from 30 to 48 hours old. *Br. abortus* was isolated from 10 of the 230 samples, the positive samples being obtained from but 3 of the 5 herds studied. Of the positive samples, an average of 2 organisms per c.c. was found, the highest count being 8.

Since September, 1929, steps have been taken by the Medical Milk Commission and public health authorities of Detroit to eliminate from these herds all animals which, on the basis of serological tests, were considered to be infected with *Br. abortus*.

This study was undertaken to answer the question: "Do animals which give negative serological tests excrete *Br. abortus* in their milk?"

The work consisted of an examination of the milk from each quarter of the udders of all animals composing the 5 certified herds producing milk for the city of Detroit. This included a bacteriological study by plating methods to isolate organisms of the *Brucella* group, and a serological study of *Br. abortus* agglutinins present in the milk serum. Records of blood serum agglutination on these animals were available through the courtesy of the Board of Health and owners of the herds, from which all data on blood serology were taken.

The specimens were taken from April, 1930, to August, 1930. Samples from each quarter, in separate sterile tubes, were immediately taken to the laboratory and examined. One-half c.c. of milk from each was placed in 0.1 c.c. portions on poured liver agar plates, making a total of 20 plates for each animal. These were placed in tall

* Read before the Laboratory Section of the American Public Health Association at the Fifty-ninth Annual Meeting at Fort Worth, Tex., October 30, 1930.

glass specimen jars in which from 5 to 10 per cent of the air was displaced by carbon dioxide. The jars were incubated at 37° C. for 3 days, at the end of which the plates were examined for the characteristic colonies of *Br. abortus*. Suspicious colonies were identified by means of cultural characteristics and agglutination with a positive serum.

After removing the milk used for bacteriological study, rennet was added to the remaining portion of the samples. On the following morning the clear milk serums which had separated were tested for the presence of *Br. abortus* agglutinins by a tube method. Five-hundredths of a c.c. of milk serum was added to 1 c.c. of antigen, giving an approximate dilution of 1-20. This dilution was run on all samples, which were kept at a low temperature so that all positive ones might be repeated in higher dilutions. The antigen used had a turbidity equal to 400 p.p.m. of silica, and was suspended in 0.85 per cent sodium chloride containing 0.5 per cent phenol. The tubes of the agglutination test proper were incubated at 37° C. and the results recorded on the second and third days.

Samples taken from each quarter of 465 animals in 5 herds were examined. The results are given in Table I.

TABLE I
RESULTS OF STUDIES ON FIVE CERTIFIED HERDS

Herd	Number of animals	Milk neg. for <i>Br. abortus</i> and agglutinins	Milk showing agglutinins	Milk showing agglutinins and <i>Br. abortus</i>
A	36	32	4	3
B	83	74	9	4
C	76	71	5	3
D	220	219	1	0
E	50	50	0	0
Total	465	446	19*	10

* These animals which were found positive by milk agglutination were immediately removed from the herds.

Of the 446 animals from which negative results were obtained in this study of their milk, only 14 have records of positive blood agglutination in dilutions of 1-100 or higher on their last blood test. Of these 14, 10 had been treated with *Br. abortus* vaccine, so the presence of agglutinins in the blood serums of these animals does not necessarily indicate infection.

Of 19 animals in which *Br. abortus* agglutinins were detected in the milk serums, all except 1 gave a record of positive blood agglutination in dilutions of 1-100 or higher upon their last blood test. The history of this animal shows a positive blood reaction in 1-500 dilution in 1923 and 1924, and abortion in 1926. Since that date, agglutinins

for *Br. abortus* have gradually disappeared, and in April, 1930, the blood serum was reported negative. Milk samples taken in May, 1930, gave positive agglutination in two quarters in 1-20 dilution; *Br. abortus* was not detected by plating methods.

Of the 10 animals from the milk of which *Br. abortus* was isolated, each gave a record of positive blood agglutination in dilutions of 1-100 or higher on the last blood test.

Table II shows the relation of the blood agglutination and results obtained in the bacteriological and serological study of their milk.

TABLE II

THE RELATION OF BLOOD AGGLUTINATION AND RESULTS OBTAINED IN THE BACTERIOLOGICAL AND SEROLOGICAL STUDY OF THE MILK

Total animals studied 465				
Blood agglutination negative 433		Blood agglutination positive 32		
Milk agglutinins negative 432	Milk agglutinins positive 1	Milk agglutinins negative 14	Milk agglutinins positive 18	
No organisms in milk 432	No organisms in milk 1	No organisms in milk 14	No organisms in milk 8	<i>Br. abortus</i> in milk 10

Positive Blood—agglutinins present in dilution of 1-100

Negative Blood—agglutinins not present in dilution of 1-100

Positive Milk—agglutinins present in dilution of 1-20

Negative Milk—agglutinins not present in dilution of 1-20

The results of the bacteriological and serological studies on the milk of the 10 animals from which *Br. abortus* was isolated are given in Table III.

A review of the results found in the separate herds shows that the milk from each animal in 2 of the herds was free of organisms of the *Brucella* group as far as could be shown by plating methods. Why were there no organisms found in herds D and E, while plating methods revealed them in the milk from 10 animals in herds A, B, and C? The probable answer is found in the original percentage of infection and the duration of the elimination process by serological tests in the separate herds. The process of elimination in herd D, on the basis of

blood agglutination, has been in progress for 24 months, whereas in herds A, B, C, and E it has been in progress only for 6 to 9 months. However, of these 4 herds, E had the lowest original percentage of infection; hence the completion of elimination has been more rapidly effected in this one than in the others.

SUMMARY

Samples of milk from each quarter of the udder of 465 animals in 5 certified herds were examined by bacteriological and serological methods in an effort to determine if animals which give negative serological tests excrete *Br. abortus* in their milk. In this series of animals, *Br. abortus* was not detected in the milk from any animal in which agglutinins were not also found in the same sample, nor was *Br. abortus* detected in the milk from any animal unless agglutinins were present in the blood serum in at least a 1-100 dilution.

A Study of the Epidemiology of Undulant Fever*

H. E. HASSELTINE, F. A. P. H. A.

Senior Surgeon, U. S. Public Health Service, Washington, D. C.

IN 1929 there were 1,305 reported cases of undulant fever in the United States. Some of these were reported through unofficial though reliable sources. Prior to 1925 a total of 128 cases was reported. In 1925, 24 cases were reported and since that year the number occurring annually has at least doubled that of the previous year. In the first half of 1930, 559 cases had been reported to the U. S. Public Health Service as compared with 256 cases for the corresponding half of the year 1929.

In 1929 the disease was present in every state of the Union. It is probable that some of the reported cases were incorrectly diagnosed, but it is almost certain that these would more than be offset by unrecognized and unreported cases. If the occurrence of cases continues throughout the current year at the rate shown in the first 6 months, the incidence rate of the disease in 1930, based upon the population of the whole United States, will be approximately 2 per 100,000, or about one-tenth that of typhoid fever. It may be pointed out that in the past many cases of undulant fever have been called typhoid fever, and as the correct diagnosis of undulant fever increases there will be a proportionate decrease in the typhoid fever rates. However, undulant fever probably will never equal typhoid fever as a public health problem in the United States, as has been reported in some European countries.

Prior to 1929 no seasonal distribution of cases was observed, each month showing an increase over the previous months except for minor variations. In 1929 the number of cases increased gradually from 27 in January to 160 in September, except for a slight drop in August. From October to the end of December they decreased. Thus far in 1930 the rise has been similar, though a greater number of cases have been reported.

From March, 1929, to March, 1930, I was engaged in Field Studies

* Read before the Laboratory Section of the American Public Health Association at the Fifty-ninth Annual Meeting at Fort Worth, Tex., October 30, 1930.

of undulant fever in various sections of the United States, and personally collected epidemiological data on 109 cases in 14 different states. Approximately two-thirds of these patients lived in cities or towns having a population of 5,000 or more, and one-third in rural districts. In the State of Iowa, Surgeon A. V. Hardy, working jointly under state and federal authority, carried on similar studies on 375 cases, making a total of 484 on which information was gathered.

The age distribution of our cases resembles that of other reported series, showing a comparatively low incidence in young children, and rapidly increasing in the period of adolescence and early adult life. The distribution between the sexes was nearly 3 males to 1 female.

TABLE I
INCIDENCE BY AGE AND SEX OF 463 CASES

Age Group	Males	Females	Total
Below 5 years	3	2	5
5-9 years	5	3	8
10-14	17	6	23
15-19	28	6	34
20-24	48	7	55
25-29	42	15	57

65-69	3	5	8
70 and over	2	4	6
	<hr/> 342	<hr/> 121	<hr/> 463

Generally speaking, the occurrence of only 1 case in a household was the rule. In 11 households more than 1 case was found, while in others an indefinite history of an undetermined fever in some previous year was obtained.

In 435 of our cases the information obtained was sufficiently complete to permit a classification into three distinct epidemiological groups: (1) Those having little or no contact with livestock or carcasses; (2) those having contact with livestock and carcasses in the meat packing industry; (3) those having contact with livestock on the farm.

The first group was composed chiefly of those living in urban communities, whose most probable source of infection was raw milk. The second was largely composed of persons living in cities, whose occupation was in some phase of the meat industry, including its by-products.

The third consisted almost entirely of persons living in rural communities, a majority being farmers. These may be conveniently called the milk, meat, and farm groups respectively.

One hundred and ninety-eight cases were placed in the milk group, of which 103 (52 per cent) were males and 95 (48 per cent) females. The meat group contained 44 cases, 43 (98 per cent) males and 1 (2 per cent) female. The farm group had 193 cases, 184 (95 per cent) males and 9 (5 per cent) females.

The Milk Group—This was composed almost wholly of professional and business persons, laborers (other than on farm or in meat packing industry) and students, the latter including school children.

The information received as to consumption of dairy products by persons in this group showed that 178 used raw milk regularly, while in 20 part of the milk used was raw and part pasteurized. Creamery butter, which is practically always made from pasteurized cream, was used by 181 (91 per cent) of the persons in this group. Nine used no butter. Cheese was used by nearly all, but rarely was the use of imported cheese found. Many different brands of American cheese were used, but no particular kind seemed to be associated with an unusual number of cases.

Generally speaking, cases of undulant fever are so scattered that it is unusual to find a group of cases associated with a common milk supply. However, in 9 occurring in Waycross, Ga., in 1929, none had significant contact with livestock, all used raw milk, and 8 used milk from the same dairy. Approximately half of the milk supply of the city was raw, and half pasteurized.

In two of the Waycross cases cultures of *Brucella* were obtained from the blood and both were of the *suis* variety. Cultures were not made from the animals in the dairy herd, but agglutination tests showed the presence of reacting animals. Since pasteurization of all milk became effective in Waycross, on March 1, 1930, there have been no new cases of undulant fever in the city. The epidemiological evidence suggests no other explanation than an infection with the *suis* variety of *Brucella* transmitted through milk.

The Meat Group—This consisted of 40 packing house employees, 2 butchers, 1 worker in a rendering plant and 1 employee of a plant manufacturing hog-cholera serum. The 1 female in this group was a packing house employee engaged in making sausage casings. The association of all the cases with pork and pork products is worthy of note. In this group 8 persons used raw milk regularly, 2 part raw and part pasteurized, 23 pasteurized milk regularly, 3 canned milk, and for 8 information was not complete.

The Farm Group—There were 193 cases, chiefly of farmers (including members of their families and farm laborers), veterinarians, and livestock dealers. One hundred and eighty-eight persons in this group used raw milk, 1 part raw and part pasteurized, 1 canned milk, and 3 no milk. In the great majority the milk was obtained from farm animals with which the patient came in contact repeatedly.

EVIDENCE OF INFECTION IN ANIMALS

In the dairy herds supplying milk to the cases of the milk group the presence of *Brucella* infection was proved by serological or cultural studies in 39. Three other herds contained animals regarded as suspicious as a result of agglutination tests. In 10 other cases the history of the presence of the infection was quite definite, though not proved by laboratory procedure. While this number seems small it should be remembered that most of this group lived in cities and had little information concerning the health of the animals from which their milk supply was derived.

Many patronized milk dealers who obtained their milk from 2 or more herds, from a milk producing area that was presumably infected. We may expect better information as to the presence of the infection in the area furnishing milk to cities, as health departments, physicians and veterinarians apply our newer knowledge of undulant fever.

The herds of cattle with which 53 of the cases of the farm group came in contact were proved positive by laboratory tests, and 11 others had animals whose blood showed a suspicious but not diagnostic reaction. In 33 additional herds the presence of the infection was reported, though not subjected to laboratory tests, and in 4 others the history was suspicious. Of 60 herds of hogs in Iowa with which cases of this group had contact, 24 were found positive on serological test, 17 suspicious, and 19 negative.

EVIDENCE OF INFECTION WITHOUT SYMPTOMS

There is probably no infectious disease that has suffered as much from misnomers as have the conditions due to *Brucella* infection. In man it has had at least 50 names, of which undulant fever is the least objectionable, but that may mislead in that the fever does not always show the wave-like curve. In veterinary medicine the term infectious (or contagious abortion) is based upon a prominent symptom, yet abortion does not always occur in infected pregnant animals. The more recent term *Brucelliasis* (or *Brucellosis*) signifies a state of infection with *Brucella* and includes all cases without regard to symptoms, geographic location, or other consideration except the etiologic

agent. It has been shown that persons may be infected with this bacterial genus without showing significant clinical symptoms.

In February, 1930, the Laboratory of Animal Pathology of the University of Illinois and the Hygienic Laboratory at Washington jointly tested the blood of 74 Illinois veterinarians, 13 workers of the Illinois laboratory exposed to *Brucella* infection, and 8 clerical employees of the laboratory, presumably not exposed. Sixteen of the 74 veterinarians showed the presence of *Brucella* agglutinins, 3 of these in dilutions of 1:80 or higher. Three of the 13 laboratory workers showed the presence of agglutinins, one in 1:160 dilution; 2 of the 8 clerical employees showed partial agglutination in 1:10 dilution.

Huddleson and Johnson³ applied the agglutination test to 49 practising Michigan veterinarians and 57 per cent showed the presence of agglutinins, 29 per cent reacting in 1:100 dilution or higher.

In Denmark, Axel Thomsen⁵ tested, by agglutination and complement fixation tests, 272 persons that had direct contact with cattle and 61 not having such contact. The no-contact group gave negative results; the contact group showed the following positive reactions to one or both tests:

NO. IN GROUP	REACTING POSITIVELY
65 veterinarians (1 yr. or more practice)	61
16 bacteriologists	10
21 herdsmen	13
25 milkers	6
23 herd owners	9
20 drovers	1
10 milk testers	1
25 butchers	5
12 meat inspectors	4

In view of such results the diagnosis of undulant fever should not rest solely upon an agglutination test but upon clinical symptoms, supplemented by serological, and, if possible, by cultural tests.

The question of the isolation and differentiation of the varieties of *Brucella* does not belong in a paper on epidemiology, other than to point out that all varieties have been isolated from human cases, and generally speaking the clinical picture produced by all varieties is similar. In a series of cases it appears that the symptoms due to the *abortus* are milder than those produced by the *suis* or *melitensis* strains, but in a single case an opinion as to the causal variety of *Brucella* can be but little better than a guess.

While it is desirable that as much light as possible be thrown on the differentiation of the varieties, it is a matter of small importance from the standpoint of the patient. The unfortunate individual finds

himself ill with a continued disabling fever no matter what strain is associated with his case.

Since all varieties of *Brucella* give an agglutination reaction against a common antigen, and when symptoms are produced all cases appear clinically identical, for epidemiologic purposes we should, at least for the present, consider the *Brucella* genus rather than the species or variety. All 3 varieties of *Brucella* have been isolated from cattle, the mammalian species of greatest importance from the immediate standpoint of the health official. Apparently the *suis* variety is able to infect nearly all species of domestic animals, and the possibility of the infection coming from unusual animal sources should not be overlooked in the epidemiologic investigations.

Up to the present, transmission from one human being to another by contact appears very infrequently, if at all. The finding of *Brucella* in the stools of patients by Amoss and Poston¹ warns us that such transmission may be possible.

Madsen² reports that in Denmark 7 out of 8 observed pregnant women aborted and in 2 of these *Br. abortus* was found in the placenta. This brings to mind the possibility of transmission from one human being to another in the course of obstetrical attendance of an infected case.

In closing, I wish to call attention to the tendency toward attributing cases to milk-borne infection. This is natural from the long period during which transmission of the caprine infection was thought to be entirely dependent upon the consumption of goats' milk. Madsen² reports that in Denmark about 40 per cent of cases are attributed to milk, and 60 per cent to contact with infected animals; while our figures show 45 per cent and 55 per cent respectively. It should be emphasized, however, that in the group attributed to contact many cases have consumed milk from their own infected animals.

The California State Department of Public Health³ in *Bulletin No. 50* states that raw milk should not be directly blamed unless one or more of the following conditions are fulfilled:

1. Shedding of *Brucella* in milk as proved by laboratory data
2. The extent of infection in the milk herd determined by agglutination test
3. Positive results from direct inoculation of guinea pigs with centrifugalized specimen of pooled milk
4. A history of recent abortions in the herd
5. A history of recent use of live organism *abortus vaccine* in the herd

In our work this standard was not applied, especially in the earlier part, but experience obtained during our investigations led us to stress the inquiry into the herd histories whenever it was possible to do so.

If the above mentioned requirements are kept in mind and inquiry is made as to the presence of *Brucella* infection in dairy herds and other farm animals, our rapidly accumulating epidemiological data will become more reliable and valuable, and our bacteriological support of the same will be greatly improved.

Italy's Maternity Insurance and Maternity-Welfare Work

THE law on compulsory maternity insurance of factory workers has been functioning in Italy for 17 years. The number of insured women increased from less than half a million in 1912 to more than a million in 1929. A still greater increase is expected to take place as the result of a law which went into effect in October, 1930, and which extends the compulsory maternity insurance to non-manual workers in a large number of occupations and to government employees.

The insured women are paid a benefit of 150 lire at the time of confinement, and those who are subject to unemployment insurance are also paid an unemployment benefit for 1 month before and 1 month after confinement, during which time they are not allowed to work.

Another feature of the maternity welfare work is the establishment of health centers for expectant mothers where they are given physical examinations and simple treatments, and are taught the rules of hygiene. A large number of such health centers have been established in the last few years by the National Children's Bureau of Italy; the National Social Insurance Fund administering the maternity insurance law has also begun to establish such centers.—*Le Assicurazioni Sociali*, Rome, 1930, 6, 5: 77, and various issues of *Maternità ed Infanzia*, official organ of the National Children's Bureau of Italy.

Minimum Qualifications for Those Appointed to Positions in Public Health Nursing^{*}

THE following definitions of desirable minimum qualifications for persons appointed to public health nursing positions are offered in the belief that they can be met quite generally by the year 1935. It is obvious that a higher level of requirements has already been reached in certain official and volunteer health organizations, particularly in the field of experience with communicable disease, and for supervisors in the matter of academic degrees. Minimum qualifications will be advanced with the years as the quality of nursing education and practical training is generally improved. Those offered here must be considered as representing a stage in development and progress.

STAFF POSITIONS

I. *For the Nurse on a Staff Providing Well Qualified Nurse Supervision*

Minimum qualifications for 1935:

- A. At least high school graduation or its educational equivalent as determined by the State Department of Education.
- B. Fundamental nursing education—namely:

Graduation from an accredited school for nurses connected with a general hospital having a daily average of 50 patients or more. Curriculum should include practical experience in caring for men, women and children, together with theoretical and practical instruction in medical, surgical, obstetrical, and pediatric nursing. Such experience may be secured in one or more hospitals.

It is highly desirable, in addition, that preference be given the public health nurse who has had training in communicable diseases (including tuberculosis and venereal diseases); psychiatric diseases and mental hygiene; and such specialties as diseases of the eye, ear, nose and throat; experience in outpatient clinics; and 2 months' affiliation with some well organized community health agency.

These services may be given in the school, as an affiliation with another school of nursing, or as a postgraduate course.

C. State registration.

For those nurses not meeting the educational and professional requirements of the above outline, occasional exceptions may be made, if profes-

^{*} Prepared by the Committee on Education of National Organization of Public Health Nursing and endorsed by the Public Health Nursing Section, the Committee on Training and Personnel, and the Committee on Research and Standards of the American Public Health Association, March, 1931.

sional training or experience has developed a wisdom and judgment which are valuable in the public health nursing field.

II. *For the Nurse Working Alone—i.e., Without Qualified Nurse Supervision*

Minimum qualifications for 1935:

A, B, and C, as above.

D. In addition it is desirable that she have had:

1. At least 6 weeks' instruction in public health nursing, preferably in one of the recognized public health nursing courses, and 1 year's experience under adequate supervision; or
2. Two years' experience under adequate supervision; or
3. A public health nursing course endorsed by the N. O. P. H. N.

Occasional exceptions may be made for those not meeting this academic and fundamental nursing standard, but such nurses should have proved their ability before being appointed for positions where they work alone, and should be expected to meet requirement D.

It is of primary importance that every public health nurse have suitable qualifications.

SUPERVISOR OR DIRECTOR IN A PUBLIC HEALTH NURSING ORGANIZATION *

I. *Supervisors*

It is expected that those appointed to positions of supervisory rank have the equivalent of the educational and professional background described as a standard for the staff nurse, namely:

- A. At least high school graduation or its educational equivalent as determined by State Department of Education.
- B. Fundamental nursing education—namely:

Graduation from an accredited school of nurses connected with a general hospital having a daily average of 50 patients or more. Curriculum should include practical experience in caring for men, women, and children, together with theoretical and practical instruction in medical, surgical, obstetrical and pediatric nursing. Such experience may be secured in one or more hospitals.

It is highly desirable, in addition, that preference be given the public health nurse who has had training in communicable diseases; psychiatric diseases and mental hygiene; and such specialties as diseases of the eye, ear, nose and throat; experience in outpatient clinics; and 2 months' affiliation with some well organized community health agency.

These services may be given in the school, as an affiliation with another school of nursing, or as a postgraduate course.

- C. State registration.
- D. At least 1 year's supervised experience in a well organized public health nursing agency.
- E. A public health nursing course endorsed by the N. O. P. H. N.

* For those nurses not meeting the educational and professional requirements of the above outline, occasional exceptions may be made if professional training or experience has developed a wisdom and judgment which is valuable in the public health nursing field.

In making promotions and new appointments to supervisory positions preference should be given to those with certain personal qualifications which, though difficult to measure, are vital to her work, such as special technical skill in the field she supervises, ability to impart information, to win confidence of staff, and to inspire voluntary requests for help; ability to delegate work with a fair balance in responsibilities assigned, and to stimulate initiative on the part of staff; ability to correlate work with that of other agencies in related health and social fields; breadth of vision covering both the aims of her profession and the work of her organization in relation to a unified community health program, with the initiative and imagination for developing new work.

II. *Educational Directors*

The educational director would need all these general qualifications together with advanced academic preparation including educational subjects if possible. It is especially important that, in addition to proven teaching ability, she shall show signs of imagination so that she can fit her individual and group teaching to the immediate needs of her staff and to the broader developments in the community's health program. She, as well as the director, must have the vision to be a few steps ahead of present practice.

III. *Directors*

The highest standard of qualification should be required of an executive director. She should have more than the minimum education required of her staff. It is desirable that she have an advanced academic preparation, preferably a college degree.

The director's experience should include at least 2 years in a public health nursing service, emphasizing family service. In addition she should have had experience as a supervisor, and, when possible, as an assistant executive director. She should have sound administrative ability to organize and direct the work.

Such a background would prove her teaching ability, her knowledge of technical skills, and her ability to cope with larger problems of organization and administration. Her distinctive contribution should be the ability to interpret the needs of her organization and of the community to her committee and board members, and to be a leader in community health developments.

The Mantoux Test

1. The Mantoux test is extremely valuable in children. It is easy to perform and is quite painless.

2. Care being taken to exclude the sources of error, . . . a negative result excludes tuberculous infection and is a comforting finding in debilitated children after measles, whooping cough, and broncho-pneumonia, and in cases of chronic cervical adenitis and so-called "intestinal indigestion."

3. A strongly positive result in young children suggests active tuberculous disease and usually justifies a bad prognosis.

4. A mild positive result indicates tuberculous infection (not necessarily disease), and children showing such a reaction would benefit from open-air treatment and increased prophylactic precautions.—The Mantoux Test, by Wilfrid F. Gaisford, *Lancet*, Mar. 7. 10

Observations on Industrial Hygiene*

A. J. LANZA, M. D., F. A. P. H. A.

*Assistant Medical Director, Metropolitan Life Insurance Company,
New York, N. Y.*

IMPRESSIONS gained from visiting industrial medical departments and inquiries received from industrialists and industrial physicians reveal a condition of affairs in the practice of industrial medicine marked by variations and dissimilarities in method and objective which at times amount to positive contradiction.

I am not endeavoring to raise the colorless banner of standardization, but it does seem that the time has come for a body such as ours to consider what should be the professional equipment of the industrial hygienist. This paper endeavors to deal with two questions: (1) Should the industrial hygienist be specially trained? (2) What are the facilities for such training and the use made of them?

A clarification of terms is essential here. We speak of industrial physicians and industrial hygienists, frequently using the terms in the same sense, whereas there is a wider difference between the two than between a general practitioner and a nose and throat specialist. Many industrial concerns consider their needs well met when they make available to their employees the services of a skilled surgeon, usually with the specific purpose in mind of satisfying their responsibilities under the compensation law. Obviously, the main requirement of the physician who undertakes this branch of industrial work is that he be a competent surgeon.

Industrial medicine has progressed far beyond this point and the majority of the larger employers of labor are looking for much more than repair work from their medical officer. We are faced by an ever growing intelligent demand from industry for the application of the principles of preventive medicine in industrial establishments and nowhere is there a greater opportunity for this branch of medical science.

The attitude of the industrialist is based on economics. Given a situation that presents a sound economic basis and an unlimited opportunity for action, there can be but one answer—progress. Here we have an industrial nation filled with mines, railways, and manufactur-

* Read before the Industrial Hygiene Section of the American Public Health Association at the Fifty-ninth Annual Meeting at Fort Worth, Tex., October 27, 1930.

ing plants of every conceivable type, commercial and financial establishments, employing 30,000,000 wage earners, most of them protected by compensation laws which are being expanded to include compensable illnesses; we have a persistent and increasing demand for the protection of the health and well-being of workers both from themselves and from those who employ them. Industry is interested not only in the treatment of disease but more so in its prevention. What a marvelous opportunity!

There is still a wholly inadequate conception of what this opportunity means in terms of the public health. Tuberculosis is an industrial problem; the prevention and control of heart disease is an industrial problem; the field of action for mental hygiene lies largely in industry, as does venereal disease control. In industry the association of numbers makes possible accomplishment on a large scale, and, by utilizing the industrial approach, preventive medicine can be carried through to the family.

The statement is frequently made by apparently well informed persons, including medical men, that any graduate of a class A medical school is competent to accept a position as medical director of an industrial establishment and fulfil the duties and responsibilities of such position in a satisfactory manner; yet I know instances of men with good all round medical training who have been serving factories for years and have been entirely unaware of the presence of occupational hazards in those plants until damage suits for occupational illness were filed against the firm employing them. I have had the experience of visiting several large concerns which had physicians in constant attendance, where in each instance there was a major hazard from lead poisoning and where also there were differing standards of diagnosis and treatment, none of which were tenable in the light of our present knowledge.

It is obvious that the physician who aspires to practise as an industrial hygienist needs special training before he can qualify in that capacity. To be sure, many industrial physicians acquire a fair working knowledge of industrial hygiene, while they are carrying on their routine duties in mine, factory, or commercial establishments. It is increasingly evident that industry is expecting from its medical officers definite activities aimed at the prevention of illness, which presuppose a type of training not possessed by the ordinary medical graduate. In other words, they expect these medical officers to be hygienists as well as physicians; but there is no more reason why a physician should essay the specialty of industrial hygiene without special training than the specialty of psychiatry, or nose and throat surgery.

The industrial hygienist should have a fair knowledge of the physiological aspects of ventilation and be able to correlate any given condition with the effective temperature chart. He should know enough about illumination to be able to measure the available light and estimate its quantity in relation to the job to be done, and be able to recognize glare and correct it. He should know under what conditions it is desirable to take air and dust samples, and what methods should be employed in taking air samples and analyzing them. He need not be familiar with the technic of analysis, but he should know when such proceeding should be resorted to, just as the general practitioner knows when a patient's tonsils should be removed though he may not practise that branch of surgery. He should know something about fatigue and posture in relation to efficient work.

The industrial hygienist should know enough about occupational poisons to be aware of those, if any, which are hazards in the plant under his care, and he should know the symptoms, methods of diagnosis and treatment of such poisons, and the means of controlling the hazards.

The industrial hygienist should have a working knowledge of statistical methods. An outstanding need in the public health field to-day is for morbidity statistics, especially in relation to occupation. There is more than one good industrial medical department with a conscientious and efficient medical director in charge, the value of whose work is largely unrecognized by his firm because of his inability to present the results in the clear-cut statistical manner which carries conviction. Over and above these technical subjects, the industrial hygienist will fall far short of his opportunities unless he appreciates the human problems of industry and can deal with them sympathetically.

He should know something of the problems of employment—whom to pass and whom to reject; what to do with the substandard man. The physical examination is becoming more and more an essential requirement for employment, and properly applied and followed up it is of tremendous benefit to the individual as well as to the industry. There is a danger, however, that industry will begin to believe that it can successfully pursue a policy of accepting and rejecting applicants for work on the same basis that the military forces recruit their strength. Nothing could be more fallacious. There are many thousands of persons who have physical handicaps of varying severity but nevertheless must work to support themselves and their families, and, moreover, are quite capable of working to good advantage if properly placed. It is unthinkable that these persons should be doomed to idle-

ness and charitable support for economic as well as humanitarian reasons. It is to the industrial hygienist that industry must turn in order to deal with this and similar questions, and industry is always ready to listen to informed and intelligent opinion.

If we admit that the physician who undertakes to practise in the preventive field of medical science as applied to industry should receive special training in the necessary branches of learning, then we must be concerned with the facilities for such training and the extent to which they are employed. Excellent courses are available, among others, at the medical schools of the following institutions: Ohio State University, Yale, Harvard, University of Pennsylvania, Columbia, and Johns Hopkins. Similar courses are available at some of the technical schools. The following brief descriptions are summarized from communications kindly furnished by officials of these schools:

Columbia—In the College of Physicians and Surgeons: 8 lectures in industrial hygiene to fourth year medical students, as part of the course in public health administration. To graduate students there is a comprehensive course, including technical instruction, as well as field work.

Yale—Three lectures in industrial hygiene; 2 conference periods, 1 factory excursion as part of the course in the principles of public health. This course embraces all medical and public health students. There is also a course of 30 hours of lectures and field work, which is elective for medical and graduate students.

Ohio State University—Senior medical students are required to take 6 hours of lectures and demonstrations in industrial hygiene. Ventilation and occupational diseases are dealt with. Since 1915 there has been available to upper class men and graduates a course in industrial hygiene, for 3 of the quarters of the year, 3 to 5 hours in each quarter. This is required of certain engineering groups, and is elective for medical, education, commerce, and art schools. There are always 2 or 3 students carrying on major research studies among registered candidates for Master of Science degrees. A number of students in the graduate school also elect minor research studies for theses.

University of Pennsylvania—Undergraduates: 3 to 4 lectures in industrial hygiene and health hazards. There is also an elective course for fourth year medical students covering 12 weeks, including lectures, laboratory, and field work. Graduates: a course in industrial hygiene, comprising 1 lecture a week for one-half year; 1 semester hour a week for one-half year; one-half day a week plant survey. The students taking this course are mostly candidates for Ph.D.; some are physicians.

Johns Hopkins—School of Hygiene and Public Health: A very complete course in physiological hygiene to furnish practical preparation for field work in industrial hygiene.

Harvard—In the Harvard School of Public Health are courses in industrial medicine embracing industrial toxicology, organization of industrial medical departments, factory sanitation and safety engineering; also courses in the physiology of respiration, including effects of dust inhalation, general circulatory physiology, neuromuscular physiology, including fatigue—all supported by laboratory experiments.

University of California—There are two courses in industrial hygiene in the department of hygiene. The students must have some prerequisites in hygiene and biology. One course is devoted to the principles of industrial hygiene, industrial physiology, prevention of occupational diseases, plant sanitation and safety. Another course embraces the organization of industrial health service, including lectures, laboratory and field excursions.

McGill University—This school offers special instruction in industrial hygiene and maintains in coöperation with the Montreal General Hospital an occupational disease clinic.

In these schools there are also courses in vital statistics which, if not included in, can be correlated with, the courses in industrial hygiene. All this is very satisfying and reflects great credit on the foresight and energy of the small band of enthusiasts who have developed these courses at the various schools.

Inquiry as to the number of persons taking these courses produces a feeling of anxiety. One university states there are 6 to 8 persons taking the work in industrial hygiene; another 4 to 8 students; another says the students vary from 2 to 8 or 10, only 1 having chosen an elective course; another had 6 students in 2 years for the industrial hygiene course; while from another comes the information that the attendance is growing steadily, but no definite number is given.

The total number is not imposing, and taking the largest figure in each case does not total 100. Moreover, not all of these are physicians or candidates for the M.D. degree. Probably less than half are physicians and of these only a portion will ever become actively identified with industry.

It is evident that the greater part of medical officers in industrial establishments are acquiring or have acquired their experience while working in the industry. Most of the good work that is being performed in industrial medical departments is built up on the pioneering efforts of courageous physicians who had vision and were not afraid to tackle something new. We are definitely emerging from the pioneering period. Not only is industry demanding more physicians, but the industrialist has learned that the degree of M.D. does not necessarily carry with it a knowledge of factory sanitation, specific occupational hazards, or how to handle men.

The medical schools are endeavoring to do their part. It remains for the physician himself, individually and collectively, to recognize the need for special training and to insist upon it as a requisite in the practice of this specialty as well as any other. Also I believe that there devolves upon this body the responsibility of defining minimal requirements for the practice of industrial medicine for the benefit of both the industrialist and the physician. The industrial hygienist

should emerge from the obscurity in which he has too frequently buried himself, and play a larger part in his community, both in his contacts with the community at large and in medical and professional associations. The presentation of his problems and achievements at medical gatherings would be of value not only to himself but to his fellow practitioners who in various capacities are continually increasing their contact with industry.

A year ago my predecessor, Dr. Rector, read an admirable paper entitled "What O'clock is it in Industrial Hygiene?"¹ In answer to his question, it is time to set off the alarm and arouse ourselves from a condition of satisfied somnolence.

Effect of Factory Work on Motherhood in Germany

A STUDY of the effect of factory work on motherhood was recently made in Germany under the auspices of the Ministry of Labor and under the direction of Dr. Ludwig Teleky, chief medical inspector of factories of Prussia, and author of numerous works on industrial hygiene.

The study covers nearly 3,000 women and 7,700 children. For purposes of comparison the women were divided into two groups: factory workers, and housewives. In making the study the officials of the Ministry of Labor were aided by physicians and welfare workers connected with the health centers attended by these women.

It was found that the women who worked during the last few weeks of pregnancy gave birth to children of lighter weight than those who stayed at home during the entire period of pregnancy. Since this was not due to a difference in the social or economic conditions the authors of the report attribute this to the effect of factory work during the latter part of pregnancy. The percentage of stillbirths was greater among the factory workers. The infant mortality rate was higher among the children of factory workers than among the children of housewives, namely 126 per 1,000 live births against 106 per 1,000 such births. The difference in the mortality rate of the above two groups is particularly high beginning with the 7th week of the child's life, that is, the time when the mother usually returns to the factory and stops nursing her child.

The investigation took place in the Rhineland where the economic conditions are more favorable and where maternity and infant welfare work is better organized than in other parts of Germany. It is obvious, in the authors' opinion, that the data concerning the working women in other cities would show more serious effects of factory work.

The authors conclude their report with a plea for an extension of the work of the health centers and a better financial provision for the working mother so as to enable her to remain at home during the last few weeks of pregnancy and a considerable part of the child's infancy.—*Die Wirkungen der Fabrikarbeit der Frau auf die Mutterschaft. Arbeit und Gesundheit*, publication supplementary to *Reichsarbeitsblatt*, Heft 14, Berlin, 1930.

West Virginia's Public Health Program*

JOHN THAMES, M. D., F. A. P. H. A.

President, West Virginia Public Health Association, Charleston, W. Va.

DURING the past few years, West Virginia has experienced a rapid growth and development of public health service. We have made substantial progress in the solution of our peculiar public health problems and have developed a system of administrative practice in some instances well adapted to our governmental organizations and our political economy. In the beginning, with special studies of certain prevalent diseases, the problem of control was very slow and unsatisfactory until the state realized that a system of public health administration must be provided that would deal with our whole public health problem rather than with any one part. As a result, the state department of health has been materially strengthened. We have gone far in the strengthening of local health service and development of local health departments under trained leadership. The fact that we have made some progress should encourage us to make further progress. Much remains to be done. Local health service needs to be intensified and improved in its efficiency. The problems of counties and areas to which the present local health organization is not readily applicable must be solved.

Health education in some form has reached most of the population of the state through the many and various organizations, welfare and otherwise, using the word health as the key word for their advancement. People are awakening to the fact that there is a way by which the state and county authorities are able to institute measures that will lessen the dangers of child bearing and protect the children against preventable diseases. This plan of procedure has been so thoroughly demonstrated where it has been tried that its wonderful results have become apparent to all. A plan to organize health service, under the direction of trained leadership, that will serve the counties and areas not receiving such services would probably interest the legislature and county courts in making the necessary appropriations for administering the service.

In the undertaking of this task of making the public health ad-

* Presidential Address, delivered before the Annual Meeting of the West Virginia Public Health Association at Morgantown, W. Va., November 21, 1930.

ministration more efficient and effective there is no single element more important than that part which the physician may play. It has been thoroughly demonstrated to the satisfaction of the health organization that the attitude of the public and medical profession must be in accord in order that it may succeed. Any method of public health administration must recognize the principle that the public health and medical organizations jointly serve the public interest.

It is now recognized that preventive medicine and the administration of public health programs constitute a specialty of medicine. The health officer is a specialist in preventive medicine. It is his obligation and duty to instruct people how to keep well, to obtain an immunity status so far as possible, and interpose the necessary barriers to the spread of infections. He should restrict his activities to his specialty so as not to infringe on the physician's rights, or violate what is known as professional courtesy. The health officer is not in competition with the physician. His services are intended to strengthen the faith and confidence of the people. The health program will do more to increase the physicians' income than to curtail it, provided they accept it, and use it for that purpose. The object is to preserve the interest of the public and profession.

People have become so enlightened by reading magazines and syndicated news articles that it is essential that they be properly directed; otherwise there is great danger of their falling into the hands of charlatans and quacks, or that they may resort to patent medicines. Experience in public health administration indicates the soundness of the statement, "the practising physician is the most essential arm of preventive medicine," because every health officer knows that he is dependent on the physicians for discovery of cases, early diagnosis, and prompt reporting. One of the saddest mistakes a physician can make is to neglect this important duty he owes to society. In some instances he will not only neglect to report but will undertake to look after the danger of spread of an infection himself, which may get beyond his control, injure his reputation, and endanger the public. Then it is we have an unwarranted criticism brought against the health authorities that cannot be explained without exposing the physician.

In the administration of any public health program it is perfectly possible for the health officer to utilize the services of physicians to the credit of the medical profession. This is done in all places where the public health program is meeting with success, and is as it should be. The only chance for conflict or misunderstanding between a public health official and practising physicians is where the health officer is not sufficiently trained to stay within bounds of his specialty, or the

physicians do not try to acquaint themselves with the duties of a health officer, the neglect of which would make it very easy to misunderstand.

Public health service does not, and is not intended to, curtail a physician's income. It has a tendency to strengthen confidence and educate people to consult a physician when otherwise they would not do so. The large number of cases referred to the physician by members of the health service will increase his income, provided he takes advantage of the opportunity. Physicians should refer to the health officer all cases of drainage, garbage and sewage disposal, and water supply, or any condition that he may suppose to be dangerous to health. He should consult with the health officer regarding the occurrence of contagious diseases in his practice. In this way, a satisfactory conclusion may be reached and measures adopted by the health official that will prevent an epidemic, thereby preserving the interest of physicians and health officer, together with protection to the public.

It is about time for the industrial corporations to understand that they are liable for certain preventable diseases occurring among their employees as they are responsible for accidents resulting from imperfect, improperly adjusted, or unprotected machinery. It is believed to be right and just for the compensation commission to have the authority to require any employer to provide sanitary living conditions for his employees, to require them and their families to be immunized against typhoid fever, diphtheria and smallpox, with a distinct understanding that when anyone is permitted to work without being so protected—which may result in a case of typhoid fever, diphtheria, or smallpox—the employer shall be considered responsible and be required to compensate the employee to the full extent of injury incurred by him or any of his family having a case of typhoid fever, diphtheria, or smallpox. While this protection is advised for anyone employing labor it can be enforced only where there is an organized health unit with a trained health officer having jurisdiction to instruct and see that the preventive measures are properly carried out.

Public health service is a business enterprise dependent upon the public for its successful maintenance. The public will not be interested in any project until it knows something about its purposes and accomplishments. Members of county courts are selected business men, elected to that position by the people. They cannot be expected to continue to make levies sufficient to support health work unless they are satisfied that their constituents, the people whom they serve, are satisfied that the health unit is for their good and the money spent for that purpose is producing good results.

People will not respond until they are approached in a proper way and understand something of its merits. As a business, health must be advertised. In addition to personal contact and other methods, newspaper publicity must be used. Short newsy informative articles thoughtfully prepared by the health officer, or an occasional interview will be accepted by newspapers. In this way, the public can be regularly informed of the activities of the service, and it gives the health officer an opportunity to perform a duty he owes the people by giving them public notice of any impending danger arising from some general insanitary condition which he desires the public to assist him in correcting. He can at least let the people know of the existence of contagious diseases and what they should do to prevent them.

This association recognizes all unofficial agencies doing any kind of health work within the state. We congratulate them on the splendid results they have achieved.

The executive committee decided, on account of the approval by the health association of the organization of the West Virginia Child Health Council, recommended by the White House Conference Committee, to discontinue for the present the organization of county health associations and allow the State Child Health Council to organize component county child health councils, which include the representatives of all existing unofficial agencies. How far they have succeeded in organizing the state we are unable to report, and beg leave to have the Child Health Council make its own report.

I desire again to remind the members of the West Virginia Public Health Association that while wonderful progress has been made, there is much to be done. Let what has been accomplished act as a stimulus for us to redouble our efforts for greater achievements. We will let nothing swerve us from our duty. Remember, when things look blue and we are inclined to become discouraged on account of insufficient funds with which to work, that there is an old motto we might apply, "He that does no more than he is paid to do, will not be paid any more than for that which he does."

I wish to thank you for the confidence reposed in me by advancing me to this high office. I gladly surrender the gavel to my successor and wish for his great success, for I feel that you will accord to him the same generous and loyal support that you have to me.

THE MEDICAL SECTION OF THE WHITE HOUSE CONFERENCE

THE Section on Medical Service, of the White House Conference on Child Health and Protection, held its final meeting in Washington, D. C., February 19–21, 1931. This was a fitting climax to a noteworthy undertaking. It brought together outstanding investigators in the field of child hygiene and made possible an exchange of professional ideas scarcely likely to occur under less auspicious circumstances. In earnestness of purpose and character of personnel it was reminiscent of similar meetings in the heyday of the American Association for the Study and Prevention of Infant Mortality. It was interesting to note how many of the pioneers in this movement were present.

Very impressive was the breadth of view, and at the same time the detailed study, evinced by various speakers in different group meetings of the Conference. The reports presented there reflected careful and exhaustive investigation and were phrased with true scientific caution. The committee reports had been thoroughly discussed in preliminary meetings, and common agreement reached upon all points presented, before the final meeting took place. Ample opportunity was afforded for discussion of controversial points in these sub-committee meetings, but fortunately all such matters were omitted from the final reports.

The popular night session, in which results of a nation-wide survey regarding utilization of medical facilities for the preschool child were

discussed, aroused a great deal of interest and commanded rapt attention. The information was presented concretely and illustrated with charts that were clearly understood. While the limitations of such a survey were pointed out, the facts presented were so convincing that they could not have failed to arouse in every representative a determination to return to his district and verify them, while at the same time devising means of looking after the preschool children more thoroughly.

The Sub-committee on Growth and Development had assembled an enormous amount of material which was thoroughly digested and admirably presented. Its discussions centered upon criterions of growth and development, nutrition, and the various factors involved in promoting growth.

The Sub-committee on Maternal and Infant Mortality sounded a challenge to all interested in child welfare. It clearly defined the limitations of present care during maternity and depicted the distance still to be traveled if proper care for mother and new-born baby is to be furnished. The need for better training of our medical students in obstetrics and the importance of prenatal and nursing care were vigorously stressed.

So much detailed technical material was presented to the Conference that it needs to be studied carefully, item by item, in devising ways and means to make proper application to local conditions. A supplement embodying the entire transactions of the final meeting was published April 6 by the *United States Daily*. This should prove a valuable reference in orientating us toward much better care of both mother and child. It is encouraging also to learn that a follow-up committee is in process of formation for the purpose of studying the reports and coming to a better understanding regarding the formulation of plans for more effective procedures. Those having the prime responsibility for the Medical Service Section are to be congratulated upon the success of its labors.

THE TYPHUS-ROCKY MOUNTAIN SPOTTED FEVER GROUP OF INFECTIONS IN THE EASTERN AND SOUTHEASTERN STATES

RECENT observations made by Dyer, Badger, and Rumreich, working at the National Institute of Health of the U. S. Public Health Service, are of great interest from a purely scientific point of view and will have a bearing on the control of certain infectious diseases from an administrative point of view.

It has been found that fleas taken from rats living in an environment which has furnished cases of typhus fever have given rise to a virus infection in laboratory animals closely simulating, or identical with, typhus fever. It has long been recognized that the typhus occurring in the eastern and southeastern states could not be attributed definitely to person-to-person infection by means of body lice, the recognized vectors of this disease in Europe, and of the same disease existing under the name of "tabardillo" in the central plateau of the Mexican Republic.

The observations referred to strongly indicate, as has been suggested by others, that rats and their parasites may play an important part in the maintenance of the focuses of typhus fever in our eastern and southeastern urban communities.

A second observation of great importance was the demonstration that certain of the cases that superficially resembled typhus were in reality due to an entirely different virus infection, one that could not be distinguished with any certainty from the infection of Rocky Mountain spotted fever of the western states, although there were minor points of difference between the two. Present evidence suggests that this infection, hitherto unrecognized in the eastern states, is transmitted by the common eastern dog tick *Dermacentor variabilis*.

Cross immunity tests clearly showed the lack of identity between this newly described virus infection and the typhus with which it had been confused for some time, but such tests did show strong affiliations with the Rocky Mountain spotted fever of the western states. With our present methods, cross immunity tests are to be looked upon as giving us practically conclusive information on such a subject.

Very briefly, the clinical distinctions between the endemic typhus, or Brill's disease, and the more recently recognized infection of the Rocky Mountain spotted fever group are: (1) In the Rocky Mountain spotted fever type of infection the duration of the temperature is irregular, sometimes as short as 7 or 8 days, and in others as long as 3 or 4 weeks, while ordinarily cases of typhus terminate by crisis rather regularly about the 14th or 15th day. (2) The eruption in the Rocky Mountain spotted fever type of infection is likely to begin on the extremities and is prone to be petechial in nature, while in the typhus cases the eruption usually appears first on the thorax and is less likely to be definitely hemorrhagic. The face is much more frequently involved in the spotted fever type than in the typhus group.

Finally, in the way of clinical distinction is the fact that while the typhus cases have long been recognized as giving almost no fatalities, the death rate in the Rocky Mountain spotted fever type, as seen in

the eastern states, is approximately 20 per cent. In general, the cases of the spotted fever type are distinctly more severe than those in the endemic typhus group.

Drs. Dyer, Rumreich, and Badger are to be congratulated on the attainment of such specifically clear-cut results, and it has been again demonstrated that the U. S. Public Health Service, through its National Institute of Health, has been alert in recognizing the importance of the problem of eruptive diseases of the virus group, and has been rewarded by the successful outcome of the experiments and observations undertaken.

HYDROGEN CYANIDE FUMIGATION

THE increased use of hydrogen cyanide, which is our best method of destroying rats and vermin, for the disinfection of ships arriving from foreign ports as well as its use on land, has brought up some interesting questions which have been studied in England.¹

The conclusions are that the absence of a pronounced taste or smell cannot be taken to show that the food is fit for use. Moist foods absorb more than those which are dry.

The fatal dose of hydrogen cyanide is set at 60 mg., and the permissible quantity has been fixed at from 40 to 50 mg. per 100 gm. It is reported that materials like dates, figs, bacon and sausages which contain from 278 to 890 p.p.m. were after ventilation lasting for a week consumed without ill effects, analyses showing as a rule less than 20 p.p.m. It appears that in foods which contain levulose, a cyanhydrin which is stable in the air and probably not toxic is formed. With dextrose, this is produced only in the presence of an alkali. When potassium cyanide is employed both form cyanhydrin. Certain foods do not deteriorate on exposure to this material, while tea, coffee, and tobacco are said to lose their flavor. Some fruits are injured, while others are not, oranges especially being unhurt, while vegetables unprotected by a thick skin, like cabbage, celery and lettuce, may show wilting.

The use of hydrogen cyanide on living plants is recommended for the destruction of insects, and as the material diffuses slowly into the plant tissue, it can be used in high concentration for effective times. Bacteria and molds are more resistant than the higher plants and HCN has little or no practical value as a disinfectant.

The report concludes that with ordinary precaution, no serious risk is involved in the use of gaseous hydrogen cyanide for the purposes mentioned. The work must be controlled by experienced operators and high concentrations avoided when possible.

SIGHT SAVING

THE Sight-Saving Review, Volume 1, No. 1, comes to our desk. Its object must appeal to everyone, whatever his particular line of endeavor may be.

The new Journal is designed specifically "to meet the needs of state and local prevention of blindness workers, educators, illuminating engineers, school physicians and nurses, safety engineers, public health administrators, industrial physicians and nurses, sight-saving class teachers and supervisors, ophthalmologists, and any one interested in the sociologic aspects of saving sight." The Editor, Lewis H. Carris, is assisted by a Board on which are a number of well known persons. The printing and make-up are excellent.

We welcome the new Journal, and wish for it the wide success it deserves.

TOO MUCH HEALTH PROPAGANDA?

ALL wise teachers of preventive medicine have recognized that there should be a happy balance between the inculcation of fear of disease and the love of health. For the average person, except those in the prime of youth, the fear of death seems to be the greatest incentive to the cultivation of health. Many teachers pursue the method of evangelists, who picture the terrors of hell and damnation until their hearers are "converted," and then dwell upon the blessings of love.

This general topic has given rise to considerable discussion through some radical statements recently published.¹ We suffer in this country particularly from fads, the prevailing ones relating chiefly to diet, because of the many statements of "food experts" whose attention is for the moment riveted chiefly on vitamins. No less authority than Hinhede has said that "America is vitamin crazy." Most of these faddists lack education; many need employment; and, without doubt,

some belong to a class not entirely normal mentally—though it must be remembered that “The mind forges strange fetters for itself,” and even so great a man as Bishop Berkeley held that this material world was nothing, and tar water was everything.

The marvelous things which bacteriology has revealed are responsible for the fact, noted particularly in women, that germs have largely taken the place of the evil spirits of old, as Aldous Huxley has pointed out.

The great prominence given to intercollegiate athletics, under the pseudonym, physical education, is also responsible for some of the present evils. We hear such expressions as “utterly fit,” “positive health”; and all sorts of preposterous food habits, exercises, and stunts are indulged in to attain this object. The number of sudden deaths of elderly men on golf links, for example, has been well parodied in the epitaph, “I was well, I wanted to be better, and here I lie.”

The article referred to states that there is an American book prescribing physical exercises for infants of 5 months, and there are parents who put their babies through absurd training. Some cases turn out well, but the relation of cause and effect has not been demonstrated. In this country, for several years past, we have devoted much attention and an enormous amount of printer's ink to periodic health examinations, and widespread campaigns have been put on by associations devoted to one form or another of health propaganda, urging early diagnosis for tuberculosis, cancer, etc., with excellent results.

The plain facts seem to be that in infancy and childhood we have accomplished a tremendous saving of illness as well as life. In the middle ages, we have postponed death, while for later years we have accomplished but little. Once before in these columns we have combated the idea, formerly taught by many physicians and even some health officers, that it was better to have the contagious diseases while young, on the ground that they were like debutantes—one must take them young or they go hard. We can but maintain the same general attitude. Such examples as the practical elimination of typhoid fever during the World War, the cleaning up of Havana, the Panama Canal Zone, and other focuses of yellow fever, must for all time prove the wisdom of proper precautions for the preservation of health, and it would be criminal not to teach them, even at the expense of evolving some hypochondriacs.

There will always be health faddists, at least until everybody is entirely normal mentally, but this will not come during the time of anyone now living. We cannot but deprecate the plan of dwelling too much upon disease and creating morbid fears which are anything but

beneficial to the general health. Fear is not a good steady diet, in either religion or health. It may "convert" some, but it does not keep them good. It acts in health matters just as it does in religion—people are good only so long as they are frightened. We are very much like the small boy who prayed at night, but said he could take care of himself in the daytime.

In spite of the damage which we believe has been done by faddists, and those who use fear of ill health for money making purposes, we believe that they have done some good in making the general public ask questions and seek knowledge concerning the body, its normal functions, and diseased conditions. It seems certain, as pointed out by one writer, that in tuberculosis, and probably other diseases, fear has lost its hold. Except in cases of phthisiophobia, fear has not been active in this matter for a long time. Consumption, like the poor, is always with us, and even the extensive campaign which has been going on for the last 25 years against this disease has not awakened an untoward sense of fear in the general public.*

Our feeling is that health teaching and measures for the protection of health must go on. Our great effort should be directed toward the elimination of half educated faddists and uneducated educators. The teaching should be done by people sound mentally as well as physically, who have had proper training, who will avoid exaggeration, and both teach and practise the precept of Saint Paul, "He that striveth for the mastery is temperate in all things."

* It is interesting to note that many religious publications have called attention to the falling off of evangelism and revivals. Only a few stars can now make more than a bare living at this calling.

AMERICAN PUBLIC HEALTH ASSOCIATION YEAR BOOK

FOR the first time in the sixty years of the Association's existence a *Year Book* has been issued and is now ready for distribution. Its aim is to provide in a single convenient place all of the committee reports presented at the Fifty-ninth Annual Meeting in Fort Worth, Tex., October 27–30, 1930, and the information concerning the organization, activities and membership of the Association which its members and others may require.

It has been issued in response to insistent demands, reiterated yearly, to publish important committee reports as soon as practicable after their presentation at Annual Meetings. Since 1911, these valu-

able contributions to public health practice and development have appeared in the *American Journal of Public Health* at some time during the year following their delivery. This practice has necessitated delay in making the material available; and even after publication, health workers have frequently been at a loss to know in which volume of the *Journal* a particular report appeared.

It has often been difficult for members to obtain needed information about the Association without consulting many books, bulletins, reports and transactions, or communicating with the central office. Furthermore, no complete list of members and Fellows has been printed since 1927, and the requests for such a roster have been numerous.

The *Year Book* brings all of this material together. The committee reports are published in full, together with the essential facts concerning the work of the Association. The corrected membership list is complete and accurate as of November 1, 1930.

This volume, therefore, should be a useful reference for every public health worker who needs to have at hand brief, concise and accurate information upon the widely varying aspects of his work. The committee personnel is appended to each report and committee members will welcome correspondence when further information is required. The book should be of importance to those members and Fellows who want more than a casual knowledge of the Association to which they belong, and to those who are frequently called upon to serve the organization, on committees or otherwise, it should be indispensable.

ASSOCIATION NEWS

MONTREAL COMMITTEES ON ARRANGEMENTS

THE Chairman of the Local Committee on Arrangements, Dr. S. Boucher, Health Officer of Montreal, announces the appointment of the following sub-committees and their respective Chairmen:

Entertainment—Dr. A. Grant Fleming
Inspection Trips—Theodore J. Lafreniere
Information, Registration, etc.—Mac H. McCrady
Finance—J. Versailles
Publicity—Dr. A. B. Chandler and Dr. J. A. Boudoin
Membership—Dr. Starkey
Ladies' Entertainment—Mrs. Creelman and Mrs. Beaubien

Plans for the registration, housing, and entertainment of the 1,500 dele-

gates expected at the Sixtieth Annual Meeting in Montreal, September 14-17, are in the hands of these committees.

Aime Cousineau, City Sanitary Engineer, is acting as Secretary of the Local Committee on Arrangements.

WESTERN BRANCH A. P. H. A.

AT the forthcoming Western Branch A. P. H. A. meeting in Seattle, May 28-30, Dr. John A. Ferrell and Dr. Kendall Emerson will represent the Executive Board of the A. P. H. A. Professor Ira V. Hiscock will also be in attendance, representing the Committee on Administrative Practice.

Dr. William C. Hassler, President-elect of the A. P. H. A., is President of the Western Branch.

NEW MEMBERS

Health Officers Section

Homer M. Austin, M.D., Columbus, O., Chief, Division of Hygiene, State Dept. of Health
Edmour Frenette, M.D., New Carlisle, P. Que., Health Officer
William B. Harrison, M.D., Memphis, Tenn., Associate Director, Local Organization, State Health Dept.
T. Douglas Kendrick, M.B., Gravelbourg, Sask., District Health Officer
Ernest A. LeBien, McHenry, N. D., Supt., Board of Health, Foster County
George J. Marbach, University City, Mo., Acting Supervisor of Sanitation
John W. McIntosh, M.B., Vancouver, B. C., Medical Officer of Health
Lloyd Moffitt, M.D., Yakima, Wash., City and County Health Officer
Dr. Eugene Mondor, Mt. Laurier, P. Que., Health Officer
E. K. Musson, M.D., Eldon, Mo., County Health Officer
M. B. Owens, M.D., Newport, Ark., Medical Director, Jackson County Health Unit
Lorenzo L. Parks, M.D., Hamilton, Ala., County Health Officer

L. A. Pequegnat, M.B., Toronto, Ont., Deputy Medical Officer of Health
Thomas E. Tucker, M.D., Monroeville, Ala., County Health Officer
Charles Williams, M.D., Montreal, P. Que., with Dept. of Public Health, McGill University

Laboratory Section

Lois Frayser, A.B., Richmond, Va., Assistant Chemist, Filtration Plant
Nell P. Hall, Springfield, Ill., Junior Bacteriologist, State Dept. of Public Health Lab.
Camille Lherisson, M.D. (Temporarily in Boston, Mass.), Prof. of Biology, School of Med., Haiti
James M. Sherman, Ph.D., Ithaca, N. Y., Professor of Bacteriology, Cornell University
William H. Swartzendruber, B.A., Iowa City, Ia., Bacteriologist, State Hyg. Labs.

Vital Statistics Section

Marjorie E. Gooch, M.S., Baltimore, Md., Statistician, Rural Survey, A. P. H. A.
Louis Weiner, E.E., New York, N. Y., Vital Statistician, Dept. of Health

Public Health Engineering Section

Victor Greiff, E.E., New York, N. Y., Disposal Division, Sanitation Dept.
 Charles H. B. Hotchkiss, M.E., New York, N. Y., Editor, Heating & Ventilating
 Augusta E. Jay, New York, N. Y., Assistant Editor, American Journal of Public Health
 Aubrey H. Perry, B.A.Sc., St. Catharines, Ont., Asst. Engr., Dept. of Natl. Health

Industrial Hygiene Section

Alexander R. Pennoyer, M.D., Montreal, P. Que., Medical Adviser, Bell Telephone Co.

Food, Drugs & Nutrition Section

Clayton P. Osgood, B.S., Augusta, Me., Milk & Dairy Inspector
 Max Paun, Detroit, Mich., Physical Education
 Rolland E. Spaun, Lansing, Mich., Bacteriologist, State Dept. of Agr.

Public Health Education Section

Estella S. Edson, R.N., Sacramento, Calif., Executive Secretary, Sacramento Tuberculosis Assn.
 Wilbur A. Heinz, A.B., Lexington, Ky., Instructor in Hygiene and Public Health, University of Kentucky
 Jean V. Latimer, B.S., M.A., Boston, Mass., Educational Secretary, Mass. Tuberculosis League
 Robert W. Osborn, Buffalo, N. Y., Executive Secretary, Buffalo Tuberculosis Assn.
 Ivan K. M. Scheepers, Johannesburg, S. Africa, Secretary, S. African Red Cross Society (Assoc)
 Savel Zimand, New York, N. Y., Administrative Director, Bellevue-Yorkville Health Demonstration

Public Health Nursing Section

Belle L. Barnstead, R.N., Hillsdale, Mich., County Nurse
 Naomi B. Blouin, R.N., Livingston, Tenn., Tri-County Public Health Nurse
 Jean M. Campbell, Austin, Tex., Field Nurse
 Ada B. Coffey, R.N., Albany, N. Y., Extension Secretary, Public Health Nursing, State Dept. of Health

Helen J. Lapham, R.N., Millerton, Okla., U. S. Indian Service Field Nurse
 Ernestine Schwab, San Francisco, Calif., Public Health Nurse, Dept. of Health
 Matilda A. Wade, R.N., Wellsburg, W. Va., Public Health Nurse

Epidemiology Section

Robert E. Hickey, M.D., Milwaukee, Wis., Director, Bureau of Communicable Disease
 Daniel F. Milam, M.D., Nashville, Tenn., Epidemiologist, State Dept. of Public Health

Unaffiliated

George Boehr, M.D., New York, N. Y., Member, Executive Comm., Committee on Public Health Relations, N. Y. Academy of Medicine
 A. H. Burkholder, Quarryville, Pa. (Assoc.)
 Joseph M. Callner, Chicago, Ill., Chairman, Public Linen Supply Assn. of America (Assoc.)

DECEASED MEMBERS

Charles J. Hastings, M.D., Toronto, Ont., Elected Member 1911, Fellow 1922, Honorary Fellow 1926
 L. C. Bulkley, St. Paul, Minn., Elected Member 1919, Fellow 1923
 Henry B. Hemenway, M.D., Springfield, Ill., Elected Member 1918, Fellow 1922
 Charles Krumwiede, Jr., M.D., Bronxville, N. Y., Elected Member 1918, Fellow 1922
 Lyman M. Ellis, M.D., Kensington, Ill., Elected Member 1919
 J. L. Ludlow, Winston-Salem, N. C., Elected Member 1903
 W. T. McArthur, M.D., Los Angeles, Cal., Elected Member 1920
 M. G. Schlotbom, M.D., Pittsburgh, Pa., Elected Member 1919
 G. C. Stevenson, M.D., Youngstown, O., Elected Member 1907
 Nathan Straus, New York, N. Y., Elected Member 1903
 Paul Preble, M.D., Ancon, C. Z., Elected Member 1923
 Arthur O. Bauss, New York, N. Y., Elected Member 1921

PUBLIC HEALTH ADMINISTRATION

HENRY F. VAUGHAN, D. P. H.

Health Program for New York State—On February 16, the Special Health Commission, appointed on May 1, 1930, by the Honorable Franklin D. Roosevelt, Governor of New York, submitted its preliminary report in which it declares that the pressing immediate needs for the commonwealth are: (1) effective local health departments with qualified personnel; (2) more effective service in the control of tuberculosis, cancer and the venereal diseases; (3) more comprehensive measures to reduce infant deaths and deaths among mothers from causes incident to childbirth; (4) further coördination of school hygiene with other health service; (5) better organization for the discovery and cure, rehabilitation and care of crippled children; (6) the extension of public health nursing throughout the state to reach the standards now in effect in a few areas; (7) protection of the public health through additional safeguards in the purification of water supplies and the prevention of stream pollution; (8) more attention to the growing problem of industrial hygiene.

The Commission includes first among its major recommendations that there be created county boards of health to provide for the rural areas and villages, and that in areas with a population of more than 50,000 the health officer must devote his entire time to the duties of his office. It is recommended that there be established three additional state tuberculosis sanatoriums, primarily to receive patients from counties which are too small in population and wealth to maintain suitable sanatoriums. The cost of maintaining patients in such institutions should be

met by the counties. It is also suggested that the State Sanatorium at Ray Brook be placed under the direction of the Department of Health. Further, a division of cancer control for the State Health Department is recommended. Other major recommendations provide for a more adequate diagnosis and treatment of venereal diseases, together with protection for the health of mothers and children, public health nursing service in rural areas, coördination of facilities for the care of crippled children, extension of industrial hygiene service, approval of plans for public water supply, and elimination of stream pollution by industrial wastes. It is recommended that the present authority of the Public Health Council to establish qualifications for certain public health personnel be extended to include other positions in the public health field.—Preliminary report of the Governor's Special Health Commission, New York State Dept. of Health, Feb. 19, 1931.

Smallpox in Williamstown—Dr. George H. Bigelow, Commissioner of Public Health for Massachusetts, reports that in a recent outbreak of smallpox which occurred in Williamstown, there resulted 9 secondary cases among 9 unvaccinated exposures. At the same time there were exposed 38 vaccinated individuals, none of whom contracted smallpox.

The first case occurred in the person of V. His wife who had been vaccinated escaped, but the baby, unvaccinated, succumbed. Mrs. V. and the baby had just recovered from chickenpox. V. visited a home in Williams-

town where he had close personal contact with 6 individuals, 5 of whom had never been vaccinated. The sixth individual, who was vaccinated, did not develop smallpox while all of the five unvaccinated became ill.

V. attended a dance in Williamstown at which 35 individuals were present. All save 1 were vaccinated. This 1 developed smallpox while the other 34 escaped the disease.

V. also visited a home in Bennington, Vt., where he had intimate contact with 4 individuals, 2 of whom were unvaccinated and developed smallpox. The 2 who had been vaccinated did not become ill.—*Special Report*, Massachusetts State Health Dept., Mar., 1931.

Typhoid Carriers in Denmark—The State Serum Institute at Copenhagen serves as the central epidemiological laboratory for the entire country and, with the cooperation of the local health boards, receives reports on all new cases of typhoid fever and pays particular heed to the carrier state. A registration system has been established for cases and carriers. There is no absolute guarantee that an individual who has recovered from typhoid fever may not be discharging typhoid fever

bacilli, even though previous examinations have shown their absence. Furthermore, the demonstration of a common source of infection will often be facilitated by the knowledge of all typhoid fever cases in the district.

All chronic carriers, that is, those in which the bacilli are demonstrated more than 1 year after the onset of the disease, are placed under strict surveillance of the health board. All patients who are still discharging typhoid fever bacilli 3 months after the onset of the disease are carried as "observation carriers." All information concerning cases and carriers is entered in a tickler file and classified as a new case, observation carrier, or chronic carrier. The State Epidemic Service finds this an extremely valuable method of curtailing the spread of typhoid fever through temporary or chronic carriers. A card index system provides accurate knowledge of the distribution of typhoid fever in Denmark; gives adequate control over the patient who is under the supervision of the Board of Health until the stools are found free from typhoid fever bacilli; and improves the accuracy of the typhoid fever statistics.—P. H. Andresen, State Serum Institute, Copenhagen, Denmark.

LABORATORY

JOHN F. NORTON, PH.D.

A LOW-TEMPERATURE INCUBATOR

DAVID B. CHARLTON

Department of Bacteriology, Oregon State College, Corvallis, Ore.

CONTROLLED incubation at levels below room temperature is required in several types of scientific work. The low-temperature incubators in use are of the water circulating type, with an ice chamber and water-jacketed working compartment. This type is useful in water control laboratories for incubation at 20° C. for gelatine culture work, and for operating at temperatures ranging from 10° C. to 25° C. or above. Recently a new type using electrical refrigeration has been developed.

The accompanying illustration shows a model which possesses several significant advantages. It was desired to have an incubator with which temperatures of 5° C. or lower could be maintained. A commercial type electrical refrigerator with a double cooling unit was used. A removable water-jacketed copper incubator was constructed to allow an air space of approximately 2" on all sides. The refrigerator has a device for approximate regulation of the temperature. This is adjusted for a temperature below that required. By means of an electric heating element on the bottom of the copper incubator and a thermo-regulator, the desired inside temperature can be maintained. The thermostat is of the rod expansion type and is regulated by means of a milled screw head from the outside on top of the incubator. A pilot lamp indicates when contact is made or broken.

The working compartment is provided with a cushioned glass door to allow inspection of the contents of the incubator without exposure to the warmer air of the room.

The one shown here has inside dimensions of 12" x 15" x 14". It has a temperature range from below 0° C. to 25° C. with a sensitivity of $\pm \frac{1}{2}^{\circ}$ C. A model with a single cooling unit would very likely be satisfactory if temperatures not lower than 10° C. were required. This model has proved satis-

factory during the past year in bacteriological work in minimal growth temperature determinations.

An important feature is that when low temperature incubation is not required, the copper incubator can be removed and the refrigerator and incubator used for their respective purposes. In regard to cost of maintenance, convenience, and automatic operation, it

possesses all the advantages of modern electrical refrigeration over the old ice-box.

The copper incubator was built and installed by J. O. Halverson of the National Appliance Company, Portland, Ore. The electrical details are not presented here as they would vary with the size of the refrigerator and type of low temperature incubation required.

RAPID AGGLUTINATION IN TULAREMIA TESTS

HERBERT E. MCDANIELS

Senior Bacteriologist, Division of Laboratories, Illinois Department of Public Health, Springfield, Ill.

THE ready agglutination of *B. tularensis* in the presence of positive serum has been noted by many workers. Hull¹ has described a rapid slide agglutination test employing a heavy bacterial suspension similar to that used by Huddleson and Abell² in their drop agglutination test for the detection of *Br. abortus* agglutinins. The importance of shaking in bringing about bacterial agglutination has been emphasized by Noble.³

In this laboratory it has been found that adequate shaking of the tubes in the ordinary routine tularemia test enables us to render a final report within about 3 minutes after setting up the test. A standard Kahn rack and tubes, or any test tube rack and tubes which will permit vigorous shaking, are suitable. The test is set up in the usual manner; it consists of a row of 8 tubes containing 0.5 c.c. each of serum dilutions ranging from 1:10 through 1:1,280, each succeeding tube having half the serum concentration of the pre-

ceding one. To each tube and a control containing 0.5 c.c. saline, 0.5 c.c. of formalin-killed antigen of a turbidity ordinarily used in macroscopic agglutination tests (BaSO₄, No. 2-No. 4) is added. The rack is held in both hands and shaken for 2 minutes as in the Kahn⁴ test, and then gently for a minute longer.

We have found this procedure gives clumps of bacteria easily visible to the naked eye and in as high dilutions as can be brought out by 2 hours in the water-bath followed by overnight storage in the ice-chest. It requires no special antigen or apparatus and considerably expedites the reporting of results. It is also applicable to other agglutination reactions, but works especially well with *B. tularensis*.

VITAL STATISTICS

LOUIS I. DUBLIN, PH. D.

Vital Statistics in Australia—At the end of 1929 the population of Australia reached the total of 6,414,372. The rate of growth during 1929 was 1.22 per cent and for 10 years 19.2 per cent, which is probably the highest rate of increase in the world. Excess of births over deaths contributed 70.5 per cent of the total increase, and net immigration 29.5 per cent. The density of population of Australia is only 2.16 persons per square mile, and varies from 1 person per 100 square miles in the Northern Territory to 20.22 persons per square mile in Victoria.

The birth rate for 1929, 20.31 per 1,000 of population, was the lowest ever recorded. Compared with many other countries the Australian rate is low, but it is fortunately accompanied by a low death rate, giving a rate of natural increase that is equaled in few countries. Extranuptial births numbered 4.70 per cent of all births registered. The proportion of multiple births is one case of twins in every 98 confinements and one of triplets in 14,242 confinements. The average number of children per mother was 2.96, against 2.99 in 1928.

During the year, 60,857 deaths were registered, corresponding to a rate of 9.55 per 1,000 of the population. This rate was slightly above the average of the previous 5 years but nevertheless compares most favorably with other countries. The principal causes of death were: heart diseases, 15.3 per cent; cancer, 10.3 per cent; violence, 6.0 per cent; cerebral hemorrhage, 5.8 per cent; tuberculosis, 5.7 per cent; nephritis, 5.6 per cent; pneumonia, 4.9 per cent. The number of deaths in

childbirth was 5.1 per 1,000 children born. The infant mortality rate for Australia (deaths of children under the age of 12 months) per 1,000 children born was 51. This rate is the lowest ever recorded in Australia and is, with the exception of New Zealand, the lowest in the world. The rate for New Zealand is 34.—*J. A. M. A.*, 96: 878 (Mar. 14), 1931.

Health Conditions in the Pacific Islands—The report of the mission entrusted with a survey of health conditions in the Pacific Islands, published by the League of Nations Health Organization, is a study of the causes of depopulation in Melanesia the correction of which will, it is hoped, provide means for the control of health in Melanesia.

According to this study Asiatic and Indian immigration was found to have a considerable influence on the disease picture. The distribution of amebic dysentery appears to coincide almost exactly with the distribution of Asiatic population. During the last 5 years Indo-Chinese labor has been introduced into the New Hebrides. A total of some 5,000 persons has been introduced and this number is increasing. Problems similar to those existing in New Caledonia and Fiji will presumably arise. In Fiji, where the Indian population is now fixed, immigration is small and indenture has ceased.

Frambesia is almost universal in Melanesia in the coastal areas. The absence of syphilis among natives and the relationship between frambesia and syphilis are important considerations in

southern Melanesia on account of Asiatic immigration. The indigenous hookworm throughout the whole of Melanesia is *Necator americanus*. It is extremely widespread but appears to be of little significance or importance in actual hospital statistics. It probably acts by reducing the resistance to other diseases. In most areas it is possible to cope with the situation by occasional mass treatment.

These conditions do not obtain when the causative organism is *Ancylostoma duodenale*. This organism is associated with Asiatic immigration. Its virulence is much more pronounced than that of *Necator*, it is much harder to expel, and it is not affected to the same degree as *Necator* by carbon tetrachloride. Filariasis is almost universal in Melanesia. It is a potent factor in economic loss. Elephantiasis, apart from the disfigurement that it causes, cripples a definite proportion of the natives and may have a minor effect on population.

It is only recently that attention has been devoted to myositis in the Pacific as a specific entity related to filariasis. The proportion of persons affected varies greatly from place to place, from 100 per cent to complete absence.

Malaria is present in northern but absent in southern Melanesia. The possibility of its introduction into Fiji or New Caledonia calls for serious consideration. Syphilis is virtually non-existent except as a possibility of the future. On the other hand, gonorrhea is fairly common. The type of the infection is unusual in that it produces few complications and the question has been raised in some localities as to whether the disease is actually gonorrhea.

Bacillary dysentery is not the scourge that it formerly was. Tuberculosis is regarded as the most important feature in the problem of depopulation in certain of the administrations in Melanesia.

As a result of the examination of the

bodies of native laborers dying at Rabaul, it has been found that 24 per cent of all indentured laborers die of tuberculosis and that pneumococcal infection accounts for an equivalent number. In other words, half the total deaths of laborers are due to pneumonia or tuberculosis.

Typhoid has not been seen in the British Solomon Islands Protectorate. It is extremely rare in Papua. It is becoming increasingly frequent in Rabaul and is engaging the serious attention of the administration. In Fiji and in New Caledonia it is a matter of the greatest importance. Measles is said to have destroyed one-third of the population of Fiji in 1874-1875 and in a second epidemic years later destroyed thousands of people, but it occurs at present without any virulent symptoms. Diphtheria is beginning to assume the characters seen in civilized countries. Scarlet fever does not seem to occur.

Students of the depopulation of Melanesia have suggested numerous causes, among them the heavy infantile mortality rate, the mortality rate at all ages from preventable disease, and the fact that the great majority of natives alternate between periods of plenty and periods of actual starvation. Medical problems of Melanesia are complicated by the low state of civilization, the belief in sorcery and the scattered nature and the smallness of the native communities.

After various experiments a central medical school was established at Fiji for the training of 40 students. The Rockefeller Foundation agreed to contribute to this a diminishing proportion of the total expenditure for 4 years.

In the matter of infant mortality it is the ignorance of the village mother that is of primary importance. The question of abortion and infanticide is a problem.

Where polygamy was the rule, certain antisocial practices have grown up since

substitution of monogamy as a result of the influence of missionaries. In some tribes a woman is deserted by her husband if she becomes pregnant, because there is no other wife to carry out her domestic and agricultural duties. For the same reason a woman sometimes continues to work until she is in an advanced stage of pregnancy. Abortion is frequent from this cause and no premature infant survives among native people.

In regard to infanticide, Melanesians have for generations terminated pregnancy by the use of many plants, most of which owe any potency they possess to the presence of tannic acid; or by mechanical means, such as the prolonged pounding of the pregnant uterus through the abdominal wall. It was found that 18 mothers died in every 1,000 births; in some areas this figure was as high as 65.

Even when children are successfully born, they have to face many hazards, such as faulty feeding, early weaning, neglect and malaria. However, the activities for the care of pregnant women, for the feeding of infants, and for the safeguarding of children up to the age of puberty represent the most direct attack on the problem of depopulation observed by the mission.—*J. A. M. A.*, 96: 788–790 (Mar. 7), 1931.

Tripping and Falling Accidents—Since 1923 organized effort to get workers to work safely in New York State has been active and continuous, but the number of compensated accidents from all causes increased 72.9 per cent. There was an important exception to this general increase. During the same period, casualties due to mechanical causes decreased from 25 per cent of the total from all causes to 15 per cent in spite of the vastly increased use of machinery. This notable result was achieved only because of the force-

ful insistence by the State Labor Department and insurance companies that mechanical hazards had to be removed.

Tripping and falling accidents are almost invariably caused by some unsafe condition. In Greater New York, nearly twice as many people are killed by falls as by typhoid and scarlet fevers, chicken pox, measles, diphtheria and croup, all combined, and twelve times as many as by fires. In Continental United States, according to the U. S. Bureau of Vital Statistics, over 17,000 people were killed by falls last year. Every 10 years more of our people are killed by falls than our total army and navy losses in battle in all our wars since the Revolutionary War, not excluding the World War.

With over 17,000 fatalities from falls per year, 70 compensable cases for each fatality, and a cost of \$410 per case—the average in New York State last year—our direct national cost for falls is over \$487,900,000. Last year it cost every man, woman and child in New York State more than \$1 to pay the compensation costs for the falls in only the industries under the jurisdiction of the State Labor Department. Falls in New York State industries last year placed 288 workers beyond the aid of any employment bureau by reason of deaths or permanent disability. In addition, 19,197 workers were placed on the unemployment list for a total of 621,346 weeks or an average of 52 weeks each. According to statistics for New York State, in total cost, total amount of lost time, and severity of non-fatal injuries, falls rank first of industrial injuries. In 1926, 1927, and 1928 they also caused the greatest number of fatal accidents.

Of the 1,088 persons killed by falls in Greater New York City in 1929, there were 12 from ladders, 32 from scaffolds, and 41 in building construction. There were 545, or slightly over one-half the total, on stairs, floors and

street. In the industries of the state, stairs, steps and level surfaces accounted for 63.8 per cent of the falls, 38.8 per cent of the lost time from falls, and 41 per cent of the compensation paid for falls. Slipping of foot, slipping or loss of balance, stumbling, misstepping or heel-catching, defective or broken surfaces, are the terms used to describe the chief causes of this largest group of falls which cost the people of this state \$3,226,190 last year. Unsafe conditions stick out all over this group. Ladders, scaffolds and staging were responsible for 17.1 per cent of the falls, 27.3 per cent of the lost time from falls, and 28.2 per cent of the compensation paid for falls. Falls from miscellaneous elevations, such as benches, boxes, structures in construction and demolition, roofs, window and wall openings, loading platforms, balconies, etc., caused 14.8 per cent of the casualties from falls, 27 per cent of the lost time from falls, and 25 per cent of the compensation from falls. Falls into excavations, pits, and openings cause 3.3 per cent of the falls, 5.8 per cent of the lost time from falls, and 4.8 per cent of the compensation paid for falls.

The most careful analysis of the various groups into which falls are classified, and over 20 years' experience in combating this type of accident indicate that unsafe conditions instead of unsafe practices by the worker are the underlying causes of nearly all falls.—H. W. Mowery, *Safety Eng.*, Jan., 1931, p. 12.

Deaths from New York Street Accidents Decrease—New York City, for the year 1930, shows the largest decrease in deaths from street accidents for any year since 1923. According to summaries compiled by the Police Department Safety Bureau and made public by Police Commissioner Edward P. Mulrooney, the total number of children killed in street accidents decreased

similarly, but the fatalities due to playing in the roadways increased from 116 in 1929 to 137 in 1930, indicating that city streets are less than ever a desirable substitute for playgrounds.

The total number of street deaths in 1929 was 1,332, while in 1930 it was 1,260, a decrease of 72. Non-fatal accidents increased from 53,450 in 1929, to 54,495 in 1930, but this increase was the smallest recorded in any year since 1923. Of these totals, the deaths of children (16 years and under) were 992 in 1929, and 939 in 1930, while for injuries only the respective figures are 39,862 and 40,819. The chief single cause of accidents continues to be "jay-walking," although this shows a decrease of 91 fatalities. Crossing the street against traffic lights, however, caused 51 more fatalities and 140 more injuries than in 1929. Reckless driving, likewise, has caused a slight increase in deaths and injuries, while collisions showed a remarkable decrease.—*Am. City*, 44: 169 (Feb.), 1931.

Infant Mortality in Porto Rico—The infant mortality rate for Porto Rico during the fiscal year 1927–1928 was 146 per 1,000 live births. During the 5-year period ending in 1928, the rate averaged 148. The highest rates were recorded in the coast towns, especially those of the west coast, and in the urban centers where the density of population is greatest. During the last 5 years the percentage of infant mortality in the west coast towns was 205; of the southern coast 164; of the northern coast 153; and of the east coast 150. In the central towns, the average was 116. Infant mortality in Porto Rico is in direct proportion to the density of population, being much greater in the urban centers than in the rural areas. The fact that infant mortality varies as to race, being higher in the negro race than in the white, partly explains the high coastal rates, since the colored popula-

tion is much less numerous in the interior than on the coast. In 1928-1929 the rate among the negroes of Porto Rico was 205 against 175 for the white population.

A factor in the high mortality of infants in Porto Rico is to be found in the loose regard in which the marriage ceremony is held in the island. Illegitimacy, as a consequence, is high, and since the mortality of infants of this class is considerably above that of legitimate children, a high rate of mortality is inevitable. In 1927-1928, the infant mortality of legitimate children in Porto Rico was 122; among illegitimate children it was 246. However, there are certain types of illegitimate children, born to parents not legally married but living together permanently, whose environment is not dissimilar to that of children born in wedlock. This explains the fact that certain places, having high rates of illegitimacy, have low rates of infant mortality; as happens in Villalba, with 27 per cent of illegitimate children, in Aibonito with 29 per cent and in Comerio and Utuado, with 25 and 28 per cent respectively. On the other hand, Santa Isabel, with 48 per cent of illegitimate children, had in 1926 and 1927 the highest infant mortality—272—in the Island, during the last 5 years.

Other factors of the Porto Rican infant death rate are indicated by an analysis of the chief causes of deaths. Prenatal, natal, and neonatal causes are relatively unimportant compared with those due to digestive disorders, diseases of the respiratory system and the communicable diseases. For example, in New York in 1924 the deaths under 1 month of age constituted 58 per cent of the total infant deaths under 1 year; while in Porto Rico they comprised but 29 per cent.

The utter ignorance of child hygiene is reflected in the fact that during the 5-year period 1923-1928, out of every 1,000 live births there were 49 deaths due to digestive diseases; 28 to respiratory diseases and 21 to communicable diseases. Of the diseases of the digestive system, diarrhea and enteritis caused 94 per cent of the deaths. The most important factor in the etiology of respiratory affections was direct contagion from older persons suffering from bronchitis and influenza. The chief diseases of the communicable group responsible for infant mortality in Porto Rico are malaria and tetanus. These two diseases caused 63 per cent of the total deaths attributable to this group. Malaria is much more common in the coast towns than in the interior. It has been estimated that not more than 6 per cent of the population of the inland towns is infected with the malaria parasite, while on the coast the average is from 25 to 35 per cent. Tetanus is, geographically, irregularly distributed.

Among the diseases of early infancy, congenital debility holds first place, having caused 86 per cent of the infant deaths in this group of diseases in 1927-1928. It is thought likely that many deaths charged to congenital debility are in reality chargeable to syphilis inherited from luetic parents. Out of 2,395 applicants for health certificates examined by the local health office of San Juan, in one year 242 or 10 per cent reacted positively to the Wassermann test. This proportion is high enough to lead to the conclusion that the infant death rate from congenital syphilis is greater than statistics indicate.—A. Fernos Iseru and J. Rodriguez Pastor, *A Survey of Infant Mortality in Porto Rico, Porto Rico Pub. Health & Med.*, VI: 151-154 (Dec.), 1930.

street. In the industries of the state, stairs, steps and level surfaces accounted for 63.8 per cent of the falls, 38.8 per cent of the lost time from falls, and 41 per cent of the compensation paid for falls. Slipping of foot, slipping or loss of balance, stumbling, misstepping or heel-catching, defective or broken surfaces, are the terms used to describe the chief causes of this largest group of falls which cost the people of this state \$3,226,190 last year. Rodriguez Pastor, A Survey of Infant Mortality in Porto Rico, *Porto Rico J. Pub. Health & Med.*, VI: 151-193 (Dec.), 1930.

PUBLIC HEALTH ENGINEERING

ARTHUR P. MILLER, C. E.

Bay Disposal and Chlorination at Newport Beach, Calif.—The separate sewer system at Newport Beach, Calif., which provides for the sand spit lying between the bay and the ocean, is discussed. The sewage was treated in an Imhoff tank and the effluent discharged into the tidal portion of the Santa Ana River. As a result of numerous complaints of objectionable odors experiments were carried out on chlorination for odor control.

A brief description is given of the field experiments and the results of pre-chlorination. A chlorine dose of 10–12 p.p.m. proved to be sufficient to control the odors and the chlorine demand was reduced considerably by improvements made in the Imhoff tank.

The effluent is now discharged into the bay without further treatment but the development of the district in the vicinity of the Imhoff tank and the increased use of the bay for bathing are beginning to necessitate further treatment of the sewage.

Figures showing the average amount of hydrogen sulphide at various points of the sewer system and the results and costs of chlorination are included.—R. L. Patterson, *Sewage Works J.*, 1930, 2, 111. From *Summary of Current Literature*, Dept. of Sci. & Indust. Res., III, 12 (Dec.), 1930.

The River as a Clarification Plant—The physical and biological effects of a river on sewage are briefly described. The amount of sewage which a river can carry without being overloaded depends on the relation of the biochemical oxygen demand of the sewage to the amount of oxygen in the river or avail-

able by diffusion from the river surface or from green plants. An equation is given from which the effect of a sewage load on a stream under normal conditions may be estimated. Solid matter affects the stream only over a short distance though its effect may be very serious. Dissolved matter may be carried undecomposed for considerable distances.

Temperature plays a great part in determining the self-purifying power of a stream. Decomposition proceeds more slowly at low temperatures than at higher temperatures. At temperatures above 20° C. it may, however, be necessary to diminish the load on the stream in order that decomposition may not proceed too rapidly for the amount of oxygen available.

The practical application of the conditions of self-purification in a stream to the problem of the necessary treatment of sewage is discussed. When treatment is necessary, a satisfactory removal of sludge is the most important point. Dams on a river improve the self-purifying power by retaining sludge and by giving more time for the decomposition of organic matter. It is essential, in considering the use to be made of a river, to treat the river as a whole.—Mahr (Address delivered before a meeting of the chief technical officials of German cities in Leipzig on Sept. 3, 1930). From *Summary of Current Literature*, Dept. of Sci. & Indust. Res., III, 12 (Dec.), 1930.

Demonstrating Proposed Treatment by Means of Miniature Plant—The water supply of Morgantown, W. Va., which is obtained from impounded

mountain and Monongahela River water, is discussed. The mountain water, which is chlorinated at the impounding reservoir, has a hardness content of approximately 15 p.p.m., and is of excellent quality. The river water, however, which is treated with lime and alum and filtered through rapid sand filters, is heavily polluted with acid mine waste water and sewage and has a hardness content frequently exceeding 300 p.p.m.

The contrast between the two waters gave rise to complaints. A report was therefore made on the possible solutions of the problem and a miniature plant, a brief description and photograph of which are given, was installed to demonstrate the various methods of treatment. Filtration of the mountain supply and zeolite softening of the river supply were recommended as the most feasible solution of the problem.—L. V. Carpenter, *Water Works Eng.*, 83: 351, 1930. From *Summary of Current Literature*, Dept. of Sci. & Indust. Res., IV, 1 (Jan.), 1931.

Lake Clusters Reveal a Florida Ground Water Supply—The appearance of salt in the well water supply of St. Petersburg, Fla., led to a survey of the geological conditions of the state, which is entirely underlain with limestone.

Peculiar conditions are caused by the formation of solution passages, sink-holes and basins in the limestone. The solution passages discharge into the Atlantic or the Gulf of Mexico. To maintain a fresh water flow toward the sea, the ground water level must be high enough to equalize, in spite of friction loss in the solution passage, the pressure of the depth of heavier sea water above the outlet level.

The causes which contributed to the reduction of the fresh water head and the consequent salting of the St. Petersburg supply and the experiences of

other communities are described. The author deals with the choice of a new source of supply for St. Petersburg in the Cosme-Odessa lake region and the precautions to be taken to control hydrostatic conditions.—M. Pirnie, *Eng. News-Rec.*, 105: 402, 1930. From *Summary of Current Literature*, Dept. of Sci. & Indust. Res., IV, 1 (Jan.), 1931.

Filter for the Purification of Water—A steam generator is built in the pipe line supplying water to the filter employed for treatment of the water. Steam from the generator, which may be supplied with water from the pipe line, is used to sterilize the filter, and the condensed water produced during sterilization can run back automatically to the generator. Illustrations of the apparatus are included.—J. Muchka, Austrian P., 118, 362; *Chem. Zentralbl.*, 2: 1749, 1930. From *Summary of Current Literature*, Dept. of Sci. & Indust. Res., IV, 1 (Jan.), 1931.

Port Sanitation—The duties of a port sanitary authority are manifold and the duties of the Port Sanitary Authority at Plymouth, England, are given as an example. The sanitary inspection of ships in dock with reference to the comfort of the crew is a regular duty. The regulation of food comes under the Authority, including both imported food and that produced locally, such as oysters. The pollution of waters by chemicals and oils is studied and methods evolved for its elimination. Medical inspection of aliens is a problem requiring considerable study and close attention, as between 16,000 and 17,000 aliens arrive during the year.

The most important branch of the Authority's duties is the control of infectious diseases. Being a port of entry only 4 days from South America, 8 days from Lagos and 1 week from India—periods well within the incubation periods of yellow fever, cholera,

smallpox and plague—the prevention of introduction of these diseases is a matter of no small importance.

The inauguration of air travel has tremendous possibilities in the way of introducing diseases and quarantine stations or a bill of health from the starting port is mentioned as means to control this channel of entry.—P. B. P. Mellows, *J. Roy. San. Inst.*, 50, 11: 712–716 (May), 1930. From *Public Health Eng. Abstr.*, X, PHA, 9 (June 14), 1930. Abstr. H. A. Johnson.

On the Influence of the Wind in the Spread of Anopheles Maculipennis—Medemblik, Holland, is situated on a slip of land projecting into the Zuider-Zee in such a way that it is inclosed by sea with the exception of a sector of 90°. In studying antilarval work, it was believed sufficient to limit this activity to 3 km. around the protected area, but in this plan no allowance was made for the wind as a factor in the spread of the mosquitoes. Experiments with stained mosquitoes undertaken to prove that the presence of the remaining anopheles in the protected area was due to an invasion from uncontrolled regions indicated an influence of the wind. The observations seem to show that anopheles are carried much farther than their need of food requires; right up to the center of the area, where a dense human and animal population stops them.

Daily catches of anopheles in the center of the protected area produced about three times as many mosquitoes on days following a wind passing over the uncontrolled breeding areas than on other days when there were only sea winds.—N. H. Swellengrebel, *Am. J. Hyg.*, 10, 2: 419–434 (Sept.), 1929. From *Pub. Health Eng. Abstr.*, X, Ma, 18 (June 28), 1930. Abstr. Arthur P. Miller.

A Rat Flea Survey of the Madras Presidency—To determine the com-

parative epidemiological rôle of the various species of fleas in plague transmission in Madras, India, field studies were made from September, 1928, to the end of January, 1929, in three areas: Hosur, Salem District; Western Half of the Bellary District and Guntakal of the Anantapur District; and Periakulam, Kambam Valley, and Dindigul.

The sanitary surveys contain detailed information regarding each area, with particular reference to rat infestation. Rat trapping measures were instituted; fleas removed from the rats caught and examined. One feature common to the three regions was the high proportion of the *X. cheopis* flea on the rats, *X. astia* being the second most prevalent. Another feature was the insanitary condition of the houses, affording excellent rat harborage. Some Hindus regarded rat destruction as irreligious and refused permission to place traps in their houses.—H. H. King, P. V. Seetharama Iyer, N. Natarajan and P. V. George, *Indian J. Med. Res.*, 17, 1: 297–334 (July), 1930. From *Pub. Health Eng. Abstr.*, X: 4 (June 21), 1930. Abstr. I. W. Mendelsohn.

Garbage and Refuse Collection and Disposal in Austria, Germany, France and Italy—Collection methods in Europe are more refined than in United States or Canada. Garbage and refuse are protected from exposure to air and wind. There are three systems of house storage used in Germany: (1) can for each householder; (2) large cans filled by several householders; (3) individual householder service or can exchange system. Wagons are specially built auto trucks. Receiving chutes are specially constructed so that garbage cans fit exactly so that no dust, garbage and refuse come in contact with air or are scattered.

Frankfort, Germany, 460,000 population, collects daily 980 cu. yd. of garbage. Twenty-two large and 2 small

trucks have replaced 100 horse drawn wagons, and the city furnishes 40,000 cans. The new system shows a saving of 25.6 per cent over the old system; it is financed by tax of 1.75 to 1.45 per cent on rental value of each house.

Paris disposes of garbage by incineration with by-products such as clinker cement and brick. Revenue pays all running expenses and interest on working capital.

Cologne has a modern plant and utilizes metals, makes steam, brick paving blocks, etc. Revenues cover all costs.

In Italy the Beccari system of transforming garbage into commercial fertilizer is much used. Fertilizer is sold at \$7 to \$10 per ton.—C. M. Morssen, *Eng. News-Rec.*, 104, 3: 109–111 (Jan. 16), 1930. From *Pub. Health Eng. Abstr.*, X, GR, 10 (July 12), 1930. Abstr. A. H. Wieters.

Milk Epidemics—There has been a remarkable decrease in epidemic diseases in the last generation in Denmark. This decrease is largely in the intestinal infections, especially typhoid fever. Paratyphoid and paradyseutery epidemics still occur and these are traced to milk in the majority of instances.

The greatest chance of infection of milk is in the cow shed at the place of production. Here infection may come from both the cow and man.

The diseases which may be transmitted from cow to man are tuberculosis (bovine type), febris undulans (bacillus abortus Bang), paratyphoid fever, bacillary food poisoning (e.g., by bac. enteritidis Gartner), foot-and-mouth disease, and mastitis (streptococci). Foot-and-mouth disease and paratyphoid fever (food poisoning group) are rare. Tuberculosis is of great importance. Infection with *B. abortus* (Bang) is much greater than is usually believed. In the last 2 or 3 years it occurred in greater frequency than typhoid or paratyphoid fever.

Diseases which may be transmitted from man to milk are divided into two groups: one composed of diseases of the pharynx and the respiratory tract, including diphtheria, scarlatina and angina; the other includes typhoid fever, paratyphoid, dysentery and paradyseutery, which are diseases of the intestinal tract.

A streptococcus epidemic occurring in Kolding in December, 1926, and a paratyphoid epidemic occurring in Odense in October, 1928, are described in detail in this article. Only 5 milk-borne epidemics have occurred in Denmark during the last 2 years, 1 streptococcus, 2 paradyseutery and 2 paratyphoid. This is remarkable in view of the fact that practically all milk consumed as milk is in the raw form. About 90 per cent of the milk produced in Denmark goes for the manufacture of butter. This milk is pasteurized.—Thorvald J. M. Madsen, *Pub. Health* (London), 43, 6: 168–174 (Mar.), 1930. From *Pub. Health Eng. Abstr.*, X, Mi, 23 (Aug. 19), 1930. Abstr. P. R. Carter.

Moulds Utilized to Make Sewage Sludge Inodorous—A description is given of sewage sludge treatment at Atlantic City, N. J. The sewage is settled in plain sedimentation tanks with a detention period of 30–45 minutes and the fresh solids are pumped on to sludge drying beds. The sludge, when dried sufficiently to permit shovelling, is removed, air-dried on land or under sheds and then stored in dark buildings. During storage, moulds, which are claimed to render the sludge finally inodorous although a musty odor is present during treatment, grow throughout the sludge even in winter.—C. G. Wigley, *Pub. Works*, 61: 38, 1930; *Pub. Health Eng. Abstr.*, July 26, 10, S, 80, 1930. From *Summary of Current Literature*, Dept. of Sci. & Indust. Res., IV, 1 (Jan.), 1931.

INDUSTRIAL HYGIENE

EMERY R. HAYHURST, M. D., PH. D., AND LEONARD GREENBURG,
M. D., PH. D.

A Review of the History of Silicosis on the Witwatersrand Gold-fields—The gold bearing area, where mining operations are carried on upon a large scale in silicious rock of "phthisis-producing" type, extends for some 30 miles on either side of Johannesburg, and is composed of a quartz conglomerate (silica, silicates, pyrites) with free silica in the original ore at 75–80 per cent. Dr. McCrae's classical paper on "The Ash of Silicotic Lungs," published some 16 years ago, showed that the mineral particles present were practically all under 5μ and 70 per cent were under 1μ in size.

The history naturally falls into 4 periods:

1. The initial period of gold mining on the Rand, from 1886 to 1899, that is, from the date of the first discovery of the reef until the outbreak of the South African War. One may fairly call this period, so far as local conditions are concerned, a period of ignorance of the dangers of silicosis.

- 2 The period of first realization of the menace of silicosis and of tentative preventive measures, from 1901 to 1910

3. The period of the introduction of a legal system of compensation for the disease, and of the trail of more systematic preventive measures, from 1911 to 1916.

4. And, finally, what one may call: The period of the "present-day" system of fully systematized measures of prevention, detection, and compensation, from 1916 to the present time.

As a mining field the Witwatersrand today stands unequalled as regards the scale on which operations are carried on, the depth the workings have attained, the organization involved, and the extent of the precautions taken to

prevent miners' phthisis. Visible dust underground is as rare as it once was common; exposure to fumes from blasting if occurring at all is accidental; and sustained efforts are being made to provide improved ventilation.

At the present time there are 45 mines of which 9 are small tribute companies. The number of European miners employed is over 10,000, and of underground colored employees over 147,000. The tonnage hoisted is over 36,000,000 tons per annum, practically all of which is broken by rock drills. The average stoping depth is 2,700 ft. The maximum depth attained is 7,638 ft. (Oct., 1929).

The combined operation of "dry" methods and "wet" methods of dust prevention since 1916 has resulted in an immense reduction of the quantity present by weight of dust in mine air, e.g., in 1915, 27 per cent of samples of air showed above 5 mg., which was reduced to 1.4 per cent in 1927. The "new Rand miner" is the man who has been carefully selected by physical examinations and supervised since 1916 and he now numbers 54 per cent of the whole body. Necessarily the incidence of silicosis has materially decreased, from an average of 3.5 per cent in 1917–1920 to 1.76 per cent in 1928–1929. The attack rate of silicosis among all miners from 1920 to 1923 was 5 per cent but among the "new Rand miners" in the tenth year of their service it was 1.3 per cent. During the past year silicosis was first detected among miners after 12 years' duration of exposure.

It is now urged that "wet" methods of dust allaying be replaced where possible by "dry" methods because of the apparent tendency of the former to increase the rate of tuberculosis. Other hazards confronted are high temperatures with high humidities, and the comparative ineffectiveness of water sprays to remove, from the air, particles of dust which are under $5\ \mu$ in diameter.

It is likely that the mines will continue for 20 or more years with other virgin ground possible, so that the fight against phthisis must be continued for many years, realizing, of course, that mechanical methods, replacing hand methods, may become an important factor not only in the reduction of the disease but in the reduction of the manual labor necessary.—L. G. Irvine, A. Mavrogordato, and Hans Pirow, *Internat. Silicosis Conference, Johannesburg, August 13-27, 1930* (Internat. Labour Off.), 33 pp. E. R. H.

The Measurement of Skin Temperature in Its Relation to the Sensation of Comfort—These experiments were undertaken in order "to find an objective physiological criterion for the determination of comfortable environmental conditions for human beings." In all, 4 subjects, 2 male and 2 female, were utilized in these experiments. Additional observations were made on the investigator, a female.

The apparatus employed for skin temperature determinations was of the thermoelectric type. Skin temperature observations were made on the forehead, the two cheeks, the sternum, and a point over the carotid artery. The subjective sense of comfort was classified by the subject on a basis of 1 to 5; 1 being uncomfortably cold, 5 uncomfortably warm, and 3 corresponding with the optimum condition of comfort.

The forehead temperature of the 4 subjects when they experienced conditions which they considered optimum

from the point of view of comfort ranged from 32.6 to 34.2°C . The temperature of the skin measured over the carotid artery varied from 32.2 to 34.0°C ., under like conditions. When the subject felt warm the forehead temperatures varied from 35.1 to 36.2°C ., and the temperature of the skin measured over the carotid artery varied from 35.2 to 36.2°C . On the other hand, when the subject felt uncomfortably cold, the forehead temperatures varied from 32.2 to 32.3°C ., while the carotid temperature varied from 31.2 to 31.9°C .—Emma France Ward, *Am. J. Hyg.*, XII, 1: 130-154 (July), 1930. L. G.

Transactions of the Industrial Health Section, 1930—At the Congress held in Pittsburgh, Pa., September 29-October 2, 1930, the officers of the Industrial Health Section were W. A. Sawyer, M.D., Eastman Kodak Company, Chairman, W. A. Colcord, M.D., Carnegie Steel Company, Vice-Chairman, and C. O. Sappington, M.D., National Safety Council, Secretary. L. R. Thompson, M.D., U. S. Public Health Service, was Chairman of the first two days' sessions, C.-E. A. Winslow, Dr.P.H., Yale University, of the third day's session, and Grace M. Heidel, R.N., New York Central Railroad Co., of the fourth day's session.

The papers presented and their authors were as follows:

Health Records in a Small Plant—*John H. Holzbog*

Coöperation Between Worker and Management in Health Programs—*C. O. Sappington*
Focal Infection and Its Relation to Fatigue and Industrial Accidents—*Nils Juell*

A Symposium, Qualifications of the Industrial Physician:

The Viewpoint of the Educator—*H. F. Smyth*

The Viewpoint of the Industrialist—*William G. Marshall*

The Physician-Administrator—*T. Lyle Hazlett*

The Viewpoint of the Health Department—*Albert S. Gray*

- Poisons of Industry—*William S. Wadsworth*
 Correct Feeding, Its Value to Industry—*Katherine Pritchett*
 Relation of Industrial Health to State Departments of Labor and Industry—*Elizabeth B. Bricker*
 Accidental Sickness—*Charles S. Prest*

Histopathology of Different Types of Electric Shock on Mammalian Brains—In this study sub-lethal electric shocks were administered to laboratory animals, after which the brains were removed and studied histologically. It was found that the nature of the lesion depended, to some extent at least, on the nature of the current used. The author's conclusions are as follows:

1. Electric shock when passed through the head produces lesions in the brain.
2. There is a correlation between the type of lesion and the electric wave form.
3. Heat plays but a minor rôle in the production of these lesions.
4. The intracranial vascular changes during a particular type of shock are consistent with the type of lesions produced by such shock.—

Raymond Morrison, M.D., Arthur Weeks, and Stanley Cobb, M.D., *J. Indust. Hyg.*, XII, 9 and 10 (Nov. and Dec.), 1930. L. G.

The Effects of Lead on the Vision—This contribution discusses the literature with reference to the effects of lead on vision, and presents references to 5 cases of lead poisoning with associated eye disorders, from the author's

experience. One of these cases, that of sub-hyaloid hemorrhage, is presented in some detail.

The author concludes that mere association of the two disorders, that is, lead poisoning and ocular disturbances, is no proof of casual relationship. He feels that there is no positive proof in the cases reported that lead was the agent responsible for the eye lesions.—Frank G. Pedley, M.D., *J. Indust. Hyg.*, XII, 10 (Dec.), 1930. L. G.

Rational Method for Calculating Records Obtained by Means of Owens' Jet Dust Counting Apparatus—The Owens' dust sampling instrument is a small portable type instrument having a very high efficiency for dust collecting. The present report deals with a study of the distribution of dust particles on the records with a view to ascertaining the proper technic to be employed in the making of dust counts so that they may be reported in millions of particles per c.c. of air.

In this study the distribution of particles on the cross-section of the record, as well as on the longitudinal section, and also at the dense ends of the section, has been studied. As a result of this study it is concluded that the actual length of the record need not be counted, since these are very close to 1 cm. in all cases; that the dense dust area at the ends of the strip need not be counted but instead that from 5 to 10 triangular areas of each record be counted which, by a mathematical process, may be converted over into numbers of dust particles per c.c. of air.—Dr. M. Kagan and Dr. W. Broumstein, *J. Indust. Hyg.*, XIII, 1 (Jan.), 1931.

Report of the Medical Officer of Industrial Hygiene for the Year Ended December 31, 1929—The report of the Medical Officer of Industrial Hygiene is always an interesting docu-

ment, and the present one is no exception to this general rule. A report is presented on the examination of 500 coal miners from the viewpoint of silicosis.

During these examinations much valuable information was accumulated on the subject of miners' nystagmus. The subject of bakers' dermatitis received some attention since approximately 20 cases were encountered during the present year. The problem of the lead hazard and hygiene in the accumulative factories continues to command considerable attention. Dr. Badham recommends that no overtime be permitted in lead processes; that only persons over 18 years of age be so employed; and that a monthly medical service be inaugurated.

Other interesting activities of the bureau during the past year include studies of arsenic poisoning, spray painting, ventilation, dust in the sandstone industry, and one investigation into a newer industrial hazard, namely, the use of X-ray machines in shops or other industrial places. This last investigation indicates that there exists a very definite hazard to machine operators, owing to insufficient protection against rays leaking through the machine walls. There is little doubt that the Division of Industrial Hygiene of the Department of Public Health, New South Wales, continues to make excellent contributions to the field.—*Report of the Director-General of Public Health, New South Wales, for the Year Ended 31 December, 1929.* L. G.

Pneumoconiosis and Tuberculosis—This is a review of the whole subject of pneumoconiosis and tuberculosis in approximately 80 pages divided into 7 portions as follows: (1) An Historical Résumé of Pneumoconiosis, (2) Types of Dust, (3) Pathology, (4) Diagnosis, (5) Prognosis, (6) Relationship between Tuberculosis

and Pneumoconiosis, and (7) Prophylaxis and Treatment.

It is quite impossible in a brief abstract to do justice to the paper, since in itself it is an interpretation and very complete summary of all the important contributions in this field.

Any one who is interested in the problem of dust and its effects will find this an invaluable reference work. The paper concludes with a bibliography of 238 references.—Henry Stuart Willis, *Medicine*, 4, 4 (Dec.), 1930. L. G.

Examination of South Coast Coal Miners for Fibrous Diseases of the Lungs—The Coal Commission required medical opinion concerning the practice of stone dusting. It was therefore desirable to determine what was the present incidence and characters of fibrosis of the lungs in coal miners as a scientific safeguard against assessing all future cases of fibrosis to the practice of stone dusting.

About 500 coal miners were examined. A marked incidence of fibrous disease of the lungs was found in one pit, and already some 12 miners have been compensated for this condition, for such disease not being due to silica dust comes under the Workmen's Compensation Act of 1926. The results of this investigation will be published.—Charles Badham *et al.* Extract from the *Report of the Director-General of Public Health, New South Wales, for the Year Ended 31 December, 1929*, p. 55. E. R. H.

Bakers' Dermatitis in New South Wales in 1929—During the investigation of 20 bakers with dermatitis, it was found that the individuals were of the allergic type and sensitive to most of the chemicals and proteins met with in the course of their work.

Routine testing was carried out with wheat flours, malt wheat flour, ammonium persulphate, ammonium chlo-

ride, treacle, malt extract, dried yeast and potassium bromate. It was found that all the bakers who had suffered from dermatitis had been using yeast foods or accelerators containing ammonium or potassium persulphate and that the outbreak of dermatitis followed a few months after the introduction of this chemical in yeast foods, a practice new in Australia.

Water suspensions or solutions of whole products were used in testing. A typical subject, when tested, shows a marked wheal and erythema to most of the substances mentioned above, particularly malt wheat flour, while the reaction to ammonium persulphate in 5 to 10 per cent solutions is a great wheal and marked erythema which persist often for days, whereas the other reactions disappear within an hour or two. Often the testing lights up a resolving dermatitis. A 1 per cent solution applied over a few minutes does not produce a marked reaction.

Individuals unaffected by dermatitis have not reacted to these substances. Does the practice of bleaching flours have any bearing on this question? A critical appreciation of the results so far obtained will be published later, but one is tempted to forecast that bakers' dermatitis in Sydney in 1929 resulted from the unfortunate association of allergic individuals with aqueous solutions of persulphate.—Charles Badham *et al.* (see previous abstracts). E. R. H.

The Use of X-ray Machines in Shops or Other Industrial Places—It was found that in the use of X-ray machines in boot departments of several city shops the erythema dose which might produce burns to the customer was over 25 minutes where all the rays come through a lead glass covering the screen, but that a leakage around the screen might lead to a burn in a shorter time. As the exposure when fitting a shoe is generally well under a minute

there would appear to be little danger unless the use were repeated on successive weeks.

The machines however revealed a very definite hazard to the operator, particularly from insufficient protection from leakage around the screen.

It was therefore recommended: (1) that all X-ray machines in shops or other industrial places should be licensed after testing and inspection by the Board of Health; (2) that the present machines be immediately protected to the satisfaction of the Board of Health; (3) that in the case of machines used for shoe fitting, a notice be posted warning customers that their feet should not be exposed for more than 3 minutes in any one month, and that the use of the machines to search for needles and such like bodies is dangerous.—Charles Badham *et al.* (see previous abstracts).

E. R. H.

Chronic Lead Poisoning in Infancy and Early Childhood—The Metropolitan Life Insurance Company, as a result of a recent inquiry among prominent pediatricists, calls attention to the large number of cases of lead poisoning occurring among infants and children. The brief note points out that a Boston physician reports 50 cases of lead poisoning among children at a Boston hospital during the past 6 years. In these cases the diagnosis was proved beyond doubt, the source of lead being the paint on cribs, woodwork and toys.

It seems obvious that the simple precaution of using zinc paints in these cases should be resorted to. Lead poisoning due to the use of nipple shields and of lead ointments on the breasts of mothers was also considered a source of poisoning by the physicians interviewed.—*Stat. Bull.*, Metropolitan Life Insurance Company, 11, 10: 4 (Oct.), 1930.

FOOD, DRUGS AND NUTRITION

WALTER S. FRISBIE

The Physiological Effects of Diets Rich in Egg Whites—Previous experiments on the physiological effects of various diets rich in protein showed that cooked, dried, commercial egg white is unsatisfactory for growth, reproduction, and lactation. In this paper a further study is reported of the effects of diets rich in egg whites. The egg white used included both a commercial dried, Chinese product, and egg white from fresh eggs. The egg white was cooked in various ways and a table shows the composition of the rations.

Albino and hooded rats were used as experimental animals. A nutritional disorder and death speedily result in young rats weaned from stock rations when fed diets rich in egg white, either cooked or raw, dried or fresh. It was found that as little as 5 per cent dried liver fed 3 days before the beginning of the egg white diet protected the rats from these symptoms.

On a ration containing 66 per cent of dried egg white, either raw, Chinese, or from raw, fresh eggs, pellagra-like symptoms later developed in the rats surviving the first few weeks, even though the rations contained 20 per cent of potent dried yeast. These symptoms were prevented or cured by 20 per cent of dried beef liver but not by 10 per cent. Lard and raw linseed oil were not effective either in preventing or curing the symptoms.

The results noted in this paper confirm previous reports suggesting caution in the use of as large quantities of raw egg white in invalid feeding as has been the common practice in many hospitals in the past. Furthermore, the fact that

many cases of eczema in children have been observed to be associated with a sensitization to egg white raises the question as to whether the early introduction of egg white into the somewhat restricted dietary of the child may perhaps need to be safeguarded with protective foods in somewhat the same way as its introduction into the diet of the rats in the present experiments.—Helen T. Parsons, coöperating with Eunice Kelly, *J. Biol. Chem.*, 90: 351 (Jan.), 1931.

The Destructive Action of Finely Divided Solids on Vitamin A—The purpose of the investigation here reported was to gain some information on the destruction of vitamin A which has been found to occur on standing. A vitamin concentrate of cod liver oil was used throughout the experiment. Fourteen powdered materials of different chemical constitution were used for the mixtures with vitamin A.

A table shows the destruction of vitamin A at different storage periods. From this table it is concluded that (1) destruction of vitamin A is general with all the powders though the rate of destruction varies; (2) the degree of destruction is the same regardless of whether the mixture is stored under carbon dioxide or air; (3) the destruction is progressive.

In view of the lability of vitamin A to oxidation, it was assumed that the destruction was due to the air adsorbed on the large surface of the powders over which the vitamin was distributed. To test this assumption, an experiment was made with nuchar, and it was found that

over 90 per cent of the vitamin was destroyed within 3 hours after mixing with the nuchar. A further test was made by removing the oxygen from nuchar and then determining whether the anaerobic char would protect the vitamin. It was found that the reduced char was as destructive as before treatment.

Experiments were also carried out with granulated lactose containing water and hydroquinone. The hydroquinone exerted a marked effect on the vitamin destruction. Only 5 per cent of the vitamin was lost in 15 days compared with 90 per cent lost in half that time when hydroquinone was absent. However, in 45 days the loss rose to 40 per cent, indicating that the inhibiting action of hydroquinone is temporary. Water was found not so effective as hydroquinone in reducing the loss of vitamin A. The author has further experiments under way to extend his knowledge as to the destruction of vitamin A.—Joseph Keats Marcus, *J. Biol. Chem.*, 90: 507 (Feb.), 1931.

The Mineral, Nitrogen and Fat Content of Some Varieties of Mature Bean Seed and of String Beans—The purpose of this work was to ascertain the copper, manganese, zinc, and iron content of some of the more common varieties of seed and string beans but it was found that only a few varieties had been analyzed for mineral matter. A table is given showing the analyses of 12 different samples, namely, navy, wax, pinto, great northern, lima, red kidney, white kidney, Burpee stringless, cut short, Kentucky wonder green beans, and Kentucky wonder edible hulls.

The mineral content of the different varieties was found to be high and rather uniform. The maximum ash content occurred in the seeds and hulls of Kentucky wonder string beans. The maximum phosphorus content was also

found in the Kentucky wonder green beans. This same sample contained approximately 3 times as much sulphur as any of the other samples. These different varieties of beans were found to be fairly well supplied with copper, manganese, zinc and iron.

It has been previously reported (Sherman, H. C., *Chemistry of Food and Nutrition*, 3d ed., 1927, p. 400) that in 1908 and 1909 when beriberi was at its worst among the Philippine Scouts the disease disappeared as a result of adding dried beans to the ration.

Experiments, performed largely upon fowls, have shown that while beef has some effect in preventing beriberi, an equal weight of beans is much more efficacious. It is probable that the curative property of beans for beriberi is associated with their high mineral content.—J. S. McHargue and W. R. Roy, *J. Nutrition*, 3: 479 (Mar.), 1931.

The Effect of the Use of Mineral Oil upon the Absorption of Vitamin A—Previous experimentation has purported to show that mineral oil in the diet interferes with the absorption of vitamin A. If this is true, its use should be restricted, and the present experiments were conducted in further study of this effect to determine the value or perniciousness of mineral oil as a laxative. Two experiments were made.

In the first part of the first experiment, rats which were late in developing xerophthalmia due to a change in the stock diet, and which weighed 190 gm. on the average, were given 1 drop of cod liver oil and 0.25 c.c. of mineral oil daily mixed with the basal diet. The mineral oil constituted approximately $2\frac{1}{2}$ per cent of the diet. Of 9 rats given this diet, 1 died from infected hydronephrosis.

Eliminating the 1 rat, the average weekly gain of the rats receiving the mineral and cod liver oil was 16 gm.;

of those receiving the cod liver oil without the mineral oil, 17 gm.; and those receiving the mineral oil with the addition of vitamin A lost 19 gm. weekly. To 1 of these rats, after a loss of 40 gm. in weight, a drop of cod liver oil was administered daily, no other change being made in the diet. Response was slow, but during the second week the cod liver oil produced a gain of 30 gm.

In the second part of this experiment, the test was repeated using more nearly standard rats—those depleted of vitamin A in 5 to 6 weeks and weighing 110 gm. The amount of mineral oil administered varied from 0.25 c.c. to 0.75 c.c. Of 5 rats fed 0.75 c.c. of mineral oil daily, the average gain was 2.6 gm. The controls receiving cod liver oil in the same amount but without mineral oil showed an average daily gain of 2.5 gm.

In the second experiment, 8 rats were used which had previously been depleted of vitamin A and which were receiving at the time of the experiment sufficient vitamin A to make gains of 2 or 3 gm. daily. Litter mates receiving the same vitamin A containing extract and which had made similar previous gains were used as controls. Five per cent of mineral oil was added to the diet of the experimental rats. Of the 5 rats given mineral oil, 4 died within a month, the fifth only maintaining its weight, probably due to its having previously stored more vitamin A in its tissues. The controls, however, continued to gain very slowly, indicating insufficiency of vitamin A.

From this it seems that rats getting only sufficient vitamin A to maintain their weight are unable to survive when given mineral oil. From these experiments it appears that rats receiving an adequate supply of vitamin A are not noticeably affected by the addition of mineral oil to the diet but that rats receiving barely sufficient vitamin A to produce a subnormal growth are ad-

versely affected. If the amount of vitamin A administered is adequate, mineral oil may be given without noticeable effects. It is suggested that if mineral oil is employed it should be accompanied by a generous amount of fat-soluble vitamins.—Jennie I. Rowntree, *J. Nutrition*, 3: 345 (Jan.), 1931.

The Effect on Foods of Fumigation with Hydrogen Cyanide—This covers the experience of the foods laboratory of the ministry of health and the work of others in connection with the retention of hydrogen cyanide in foodstuffs after the use of that substance for fumigation purposes. While possessing no germicidal or fungicidal properties, hydrogen cyanide is admirably suited to most of the requirements of an ideal fumigant for the destruction of rats, moths, weevils, and other vermin and insects in such locations as the holds of ships. It exerts no deleterious action on fabrics, painted objects or metals, is highly efficacious and is readily dispersed.

Three objections attend its use—the lack of a definite characteristic odor or other warning property, its high toxicity for man and the domestic animals, and its entry under some conditions into foods in amounts that may cause harm to the consumer or cause the decay of the food.

The amount of hydrogen cyanide constituting the threshold of danger to man cannot be fixed with definiteness. As little as 10 mg. per 100 gm. of food is cited as a possible harmful quantity. The author cites many instances of foods containing a higher amount of hydrogen cyanide than this possible minimum.

Dates, figs, honey, cocoa, bacon and sausages (all foods with a high moisture content), tested after having been aired 24 hours after fumigation, have proved to contain from 278 to 890 p.p.m. of hydrogen cyanide to air.

Fumigation by means of hydrogen cyanide carried out in excess of requirements, particularly when used on fresh fruits or vegetables, may lead to commercial destruction or damage by interference with normal respiratory processes, or by the modification of characteristic odor or tastes. The danger of hydrogen cyanide poisoning of foods stands in relation to the quantity of gas, the duration of application, the moisture content of the foods, the size of the particles or units of foods, methods of packing, and the period of ventilation after fumigation.

Foods treated with not more than 1 volume of hydrogen cyanide in 200 volumes of air, with subsequent exposure to the air, do not usually contain more than 20 p.p.m. of the intoxicant to the food products. Computation of hydrogen cyanide concentrations in fumigation are usually reckoned in terms of the weights of the liquid or solid hydrogen cyanides per unit of space fumigated. This is in contrast to

methods usually employed with some other liquid intoxicants (such as benzene), for which computations are based on parts of the gas formed on evaporation, having a vapor pressure equal to air under given conditions of temperature and barometric pressure. Relative toxicities are thus not always obvious in such terms as "parts per million."

The final estimate as to practical hazards entailed is indicated in the prefatory note by Sir George Newman, which says in part:

If the process is skillfully applied and due precautions are taken to prevent excessive absorption of gas, it would seem that no serious risk to health is likely to be involved. It must, however, be emphasized that indiscriminate treatment of food with hydrogen cyanide by inexperienced operators may be fraught with real danger to themselves and to the eventual consumer of the food.—

G. W. Monier-Williams, *Reports on Public Health and Medical Subjects*, No. 60, Abstr., *J. A. M. A.*, 96: 635 (Feb. 21), 1931.

CHILD HYGIENE

RICHARD A. BOLT, M. D., DR. P. H.

THE Section on Medical Service of the recent White House Conference on Child Health and Protection* has made such a notable contribution to our knowledge of the resources available for child hygiene throughout the country that its findings should be brought at once to the attention of all those working for the welfare of the child. A follow-up committee of this Section has been authorized by Chairman Wilbur

... to get over to the country at large as quickly as possible the importance of applying the knowledge we already possess and for which machinery exists; to consider all the implications of the reports; to determine definitely where further studies are required and to stimulate them; to determine the avenues through which the recommendations made by the Section can be most effectively put over and to determine the soundness of the methods employed in applying the knowledge we have.

It is timely, therefore, to place before the readers of the *Journal* some of the outstanding findings and recommendations of the Medical Section. The Committee on Prenatal and Maternal Care presented a very complete report, the general recommendations of which are as follows:

1. That there be improvement of obstetrical teaching of physicians and nurses.
2. That there be encouragement of post-graduate teaching of obstetrics, both in courses of 3 years' duration or less, by lectures and discussions in county, district and state society meetings and by means of extension courses.
3. That the publication be encouraged of more papers in medical journals on obstetrical

subjects, especially regarding the nature and need for maternal care.

4. That there be urged the licensure, education, annual registration and supervision of midwives in those states where midwives are attending confinement cases.

5. The adoption by all hospitals admitting obstetrical patients of the minimum standards for general hospitals caring for obstetrical patients as outlined in the American College of Surgeons Year Book for 1927.

6. That all obstetrical hospitals and nursing homes be licensed and supervised.

7. That professors and instructors of obstetrics continue to emphasize in their teaching and practice the necessity for conservative measures in obstetric delivery and warning against surgical interference without consultation.

8. Continued education of the laity to the necessity of adequate prenatal, intranatal, and postnatal care in obstetrics, and to the danger of abortions, toxemias, and infections.

9. That there be a joint committee on maternal welfare representing those national organizations having active maternity programs for the purpose of close correlation of the programs, agreement as to standards involving medical, nursing and other professional procedure, principles of organization and methods of application.

10. That national agencies agree on the content of a complete maternity program, as outlined in the complete report.

11. That national agencies review their opportunities to assist in maternal care programs, as suggested in the complete report.

12. That each community be encouraged to provide adequate facilities for maternal and neonatal care.

SUGGESTED OUTLINE OF A MATERNITY PROGRAM PART OF A GENERAL PUBLIC HEALTH SERVICE

Purposes:

Education of community in nature and need of prenatal, delivery and postpartum care.

Provide adequate medical, social and nursing care, whether in home or hospital, for these periods.

* For full report of proceedings see *Official Proceedings of the Section on Medical Service of the White House Conference on Child Health and Protection, Washington, D. C., February 19-20-21, 1931*, supplement to *United States Daily*, VI, 29 (Apr. 6), 1931, Washington, D. C.

Have every expectant mother under medical supervision.

Organization:

Coördination of all agencies interested in maternity and infancy work. There are two types of organization—the official, administered by the department of public health, and the unofficial, administered usually by a voluntary nursing organization. In either an official or unofficial organization the following agencies should coöperate:

Official:

State and local health departments
State and local public health nursing organizations
Local governing board of the district
Board of Education (coöperating with general health program)

Unofficial:

Local medical and dental societies
Nursing associations
American Red Cross
Welfare agencies
Parent-Teacher Association
Federated Women's Clubs
Men's clubs
Junior League
Church groups

Health Center:

Hospital, if possible
Standard equipment and supplies
Standard record forms
Prenatal
Infant
Preschool

I. Prenatal Care:

Medical:

Private physician whenever possible
Nurse assistant

Clinic:

Department of public health—state and local
Hospital
Private agency
Obstetrical Standards
Laboratory:
Urinalysis
Wassermann
Neisserean
Hemoglobin
Blood cell count as indicated
Thyroid—basal metabolic tests, as indicated

Dental:

Private whenever possible
Clinic

Nursing:

Public health nurse
Institutional

Qualifications

Standards for service
Center
Home visits
Social worker

Educational:

Group instruction and demonstration
Materials and outlines for course
Literature

II. Delivery Care:

Home—Sterile supplies and preparation of room
Physician
Nurse, private or public health
Hospital—maternity department—standards
American College of Surgeons

III. Postpartum Care:

Medical—examination
Nursing
Breast feeding

IV. Referring the child to:

Pediatrician
Infant Welfare Station

ASSISTANCE WHICH NATIONAL ORGANIZATIONS MIGHT GIVE IN A MATERNITY PROGRAM

I. Stimulate interest of local physicians, dentists and nurses in the value and need of prenatal care

In close coöperation with:

State and local departments of health
State and local medical societies
State and local nursing organizations
State and local dental societies

Through:

Articles in state, medical and dental journals
Speakers at state and local society meetings
Physicians
Dentists
Nurses

II. Education of laity in nature and need of maternity care

Publicity through:

Magazines
Local papers
Extension services
Men's and women's club programs through:
State board of health
State medical associations
State public health nursing association
State dental associations
Speakers on special subjects
Articles for local newspapers
Material for local physicians who address groups
Programs for study groups

Literature:

(This probably should be provided by the state, but it seems that there should be *standard* publications on the subject for the public health agencies)

Exhibit material

III. Provide postgraduate education

1. Medical—for general practitioners

Courses:

a. Institutes—through state departments of health and state medical associations

b. Medical colleges

Prenatal care

Delivery care

Postpartum care

2. Dental

Nutrition and teeth

Advice and dental care for the expectant mother

3. Nurses

Institutes—through state division of public health

Nursing and state nurses associations

Maternity care

Infant care

Teaching prenatal care to groups

Outlines for group instruction

Demonstration material

IV. Improving type of midwives

Education

Licensing, annual registration, supervision—state responsibility

Annual refresher courses

Outlines and material

V. Stimulate interest in establishment of whole-time health units

Medical organizations

Dental organizations

Nursing groups

Governmental boards

Laity

Demonstration of complete maternity program

Bring maternity departments of all hospitals up to American College of Surgery minimal standards

Revision of stillbirth and maternal death reports

Make septicemia universally reportable

The report of the Subcommittee on Health Centers* was enlightening and gave an excellent picture of the distribution, scope and influence of health centers throughout the United States.

NUMBER AND DISTRIBUTION OF HEALTH CENTERS

The distribution of the 1,511 health centers throughout the country, according to states from which questionnaires on health centers were returned, is as follows: New England States, 295; Middle Atlantic, 550; East North Central, 266; West North Central, 63; South Atlantic, 162; East South Central, 49; West South Central, 59; Mountain, 40; Pacific, 117.

These centers are carried on, 643 directly by official (usually municipal) agencies; 636 by nonofficial agencies and supported by voluntary funds; and 232 are called "co-operative," which means that both official and volunteer agencies are concerned with the support of the centers. The number of independent units conducting work at health centers is considerably larger than the figures indicate, as in a number of instances an organization in a large city may carry on work in multiple centers and make a single report embracing the total volume of work.

Seven hundred and twenty-five, or 48 per cent of the total number, were directed by nonofficial organizations; 729, or 52 per cent, by county or municipal departments of health; and considerably smaller percentages by the American Red Cross, various hospitals, child health organizations, case-working agencies, tuberculosis associations, etc. Many of the health centers conducted under the above auspices were in affiliation with other organizations, official or voluntary.

THE CHILD HEALTH CENTER AN APPROVED MEANS OF HEALTH PROMOTION

The child health consultation—whether at a permanent or temporary locale—is becoming an accepted means of bringing the infant or young child to an accredited physician for physical examination and advice, for the promotion of health and for the detection of disease or of bodily defects. Treatment is not undertaken in a child health center. If disease or remediable abnormality is discovered, the patient is referred to a physician or hospital for the desirable curative treatment.

The experimental stage is nearing its end. There seems to be general agreement that the periodic physical examination of the young child throughout its formative years is desirable and that the health center provides a method to accomplish this purpose for those children in families of limited means.

* Presented by Dr. J. H. Mason Knox.

THE CENTER AS A HELP TO PHYSICIANS

We believe that a small proportion of the children examined at these consultations have been under regular medical supervision before, that the practice of the physicians of the community is rarely interfered with by the examinations conducted at a health center, but on the contrary that, as a result of the health center, local physicians receive at their offices many patients who would not otherwise have consulted them. Moreover these referred children in need of treatment are, on the average, suffering from less advanced disease and from less severe physical defects than would have been the case had they deferred coming until brought by their parents without the suggestion of the health center.

We believe that the centers or conferences should receive only infants and children supposedly well and that sick children and those in need of corrective treatment should be referred promptly to physicians or hospitals.

PREVENTIVE CARE A COMMUNITY
RESPONSIBILITY

The majority of the children brought to the average health center are from families of limited means. We believe that a determination of their physical condition and the furnishing of advice in health matters is as much a community responsibility as is the offer of free elementary education. The latter is frequently hindered or nullified because the physical or mental status of the pupil has not been ascertained.

As has been true in other kinds of philanthropic endeavor, the first child health centers were the result of the vision and interest of private individuals or various charitable organizations, industrial plants, hospitals, and similar groups. This accounts in part for the many variations in the emphasis which is placed upon certain forms of activity carried on in different centers and for the variation in the composition of the staffs. Each has developed as the special needs of the child popu-

lation of the given community impressed the patrons.

This method of development in the main has been of advantage, for it has led to the trial of many forms of service in the centers, the value of which could only be determined by experience.

It would appear that further attempts should be made to set up certain standards of operation in order that the work of the many centers may be comparable.

Gradually the wisdom of expending public money for this purpose, either as grants to existing centers or for the establishment and maintenance of child health centers or consultations as part of a public health program, has been recognized.

In addition to the 6,198 child health centers and the numerous itinerant conferences maintained by the bureaus of child hygiene, 693 of the 1,511 permanent centers studied by our committee receive their principal support from public funds. Many others receive part of their support from the same sources.

RELATION WITH HEALTH OFFICIALS AND
COMMUNITY ORGANIZATIONS

Our studies indicate that even where the centers are established and maintained by private funds they very generally cooperate actively with neighboring agencies operating in the fields of health and social service. We believe that it would be advisable to go further and make each health center a co-ordinated part of a public health program with the cooperation, or under the supervision, of the local official health agency, certainly in those instances where there is a full-time health officer responsible for health conditions in his territory. Such an official should use the center or the consultation as far as practicable in determining the physical condition of the young children who are not under the regular care of their own physicians. This official use of the center will broaden its work and make it of greater value in improving the sanitary standards of the child population.

PUBLIC HEALTH NURSING

EVA F. MACDOUGALL, R. N.*

This Will Help the County School Nurse—The Children's Fund of Michigan recommends the following as a simple first aid kit for rural schools:

Container: A small tin or pasteboard box with a cover. (A candy box will do)

Contents: 1. A half ounce bottle of 2 per cent mercurochrome with a rubber stopper and a glass rod 10c
(In districts where there might be objection to an antiseptic, use liquid green soap for cleansing)

2. One tube plain vaseline 10c

3. One yard of $\frac{1}{2}$ inch adhesive 10c

4. One two-inch bandage 15c

5. One-half dozen safety pins 5c

Total 50c

Articles which may be contributed by the children as they become interested in the use of the kit:

1. Toothpicks for cleaning nails
2. A small brush for use in scrubbing hands
3. Blunt scissors
4. Old muslin which has been boiled and ironed with a hot iron, then wrapped in freshly ironed newspaper
5. One square yard of old sheeting for arm slings
6. Old newspapers for making a splint for a broken arm
7. A stick and a stone for a tourniquet—

A Simple First Aid Kit for Rural Schools, From Children's Fund of Michigan, *Michigan Public Health*, XIX, 1: 18 (Jan.), 1931.

Teacher Training Courses for Home Hygiene Instructors—Public health nurses are being called upon more and more to teach classes in health and

hygiene. Some of the states require that each student before graduation from high school complete one unit in a health subject, and the school nurses are often asked to teach this course. The preliminary professional training of the nurse seldom if ever includes any special preparation for teaching. Some have fortunately had teaching experience before entering the profession of nursing, but that is the exception rather than the rule.

Since 1908, the American National Red Cross has organized and taken the responsibility for furnishing teachers for classes in Home Hygiene and Care of the Sick. Last year there were 3,233 classes taught in more than 1,000 different communities—2,085 of these classes were taught in the schools. Over 1,500 graduate nurses were authorized as home hygiene instructors. So few nurses are generally prepared to teach, that the American Red Cross, in order to meet its responsibility to provide teachers for the classes, has organized teacher training courses in several universities. These are given during the summer when many nurses are free to attend. Courses cover theoretical work in Principles of Teaching and also practical work in the Methods of Teaching. For those nurses who are expecting to teach classes in Home Hygiene and Care of the Sick a preparatory course of this kind is invaluable. There is an immeasurable benefit derived from being able to apply the essentials of teaching to the actual practise teaching of health subjects under the expert guidance and supervision of skilled instructors.

The Teacher Training Courses for

* Please send printed matter or other material relating to public health nursing to Eva F. MacDougall, 6 State House Annex, Indianapolis, Ind.

Home Hygiene instructors are being offered this summer at:

Pennsylvania State College, State College, Pa.,
June 29 to August 7 inclusive

Colorado Agricultural College, Fort Collins,
Colo.,

July 6 to August 14 inclusive

University of California, Los Angeles, Calif.,
June 22 to August 1 inclusive

The course at the University of California is restricted to nurses in the Pacific Branch Area of the American Red Cross.

Many nurses keenly appreciating their need of definite training in teaching have taken advantage of these courses. Application to the American National Red Cross for enrollment in the Teacher Training Courses should be made previous to the opening of the various summer schools.

HELEN BEAN

Public Health Nursing Rural Teaching Center, St. Francois County, Mo.—St. Francois County is situated about sixty miles south of St. Louis, and is in the heart of the "Lead Belt," which produces one-eighth of the lead supply of the United States. Lead mining, therefore, is the chief industry. Some farming is carried on in the northern and southern parts of the county; and tiff-digging and tie-hacking furnish employment to a few.

Although Farmington is the county seat of St. Francois County, Flat River was chosen as headquarters for the County Health Department, because it is the center of population and also the geographical center of the county. Flat River itself has a population of 8,000, but is unincorporated. The county has a population of 36,000, and covers 458 square miles.

The St. Francois County Health Department began its work in July, 1922, and consisted of a full-time county health officer, one nurse, a sanitary officer, and an office clerk. As the work

has grown, nurses have been added to the staff. At present there are three staff nurses, and a chief nurse.

The county is divided into three nursing districts. The nurse in the Farmington district has office space with the Farm Bureau agent in the Court House. The nurse in the Bonne Terre District has a small building donated by one of the lead companies; and the nurse in the central district has her office at county headquarters in Flat River.

The present budget for the County Health Department is \$20,000. This is contributed by the International Health Board, the Missouri State Board of Health, the county court and the two lead companies. The lead companies contribute 80 per cent of the total amount.

The teaching center was opened in Flat River in January, 1930, with Maud Tollefson as chief nurse and supervisor of student experience. Nurses of one group who are eligible for this experience in rural nursing are the students enrolled for the Washington University course in public health nursing. For this field work they receive credit toward the Certificate in Public Health Nursing. Certain other graduate nurses, especially qualified both professionally and personally, are also accepted. They must apply for admission to Pearl McIver, State Supervising Nurse of the Missouri State Board of Health. Students from either group may apply for the Rockefeller stipend of \$90 a month. This has been granted to nurses who wish to do rural public health nursing in Missouri.

Since a broad generalized program is carried out in St. Francois County, the students have the opportunity to observe or participate in the following activities: writing and filing of records and reports, and other routine office work; community organization; infant and school hygiene; communicable dis-

ease control; sanitation; clinic work; group teaching, and other health education activities.

One student is assigned to each staff nurse, and lives in the district to which she is assigned. During the first 2 weeks, the student observes the work of the staff nurse, attends three 2-hour lectures a week given by the County Health Officer, Dr. W. W. Johnston, and has group and individual conferences with the chief nurse.

During the next 2 weeks the school nursing demonstrations are given by Miss Tollefson, and the students spend most of their time in school work. They are permitted to work alone as soon as they are able. During the last month the students work alone, under periodic supervision. Each is assigned definite pieces of work and is held responsible for the accomplishment of these assignments.

The demonstrations continue once a week during the last 4 weeks, and cover the other types of service in the county. Individual and group conferences are held at suitable times to give the students an opportunity to discuss the work accomplished and to ask questions. The students attend also the regular weekly staff conference and a few special lectures. One lecture is given by Dr. Emmett Hctor, psychiatrist at State Hospital No. 4 for the mentally diseased, at Farmington.

Besides keeping the daily and monthly reports required by the State Board of Health, the students keep a field experience record of all activities: reading, lectures, conferences, observations, visits, practice, etc. Each student also works out some project of especial interest to her.

Field trips to the county institutions and other points of interest are arranged, and county officials and other cooperating agencies are visited. The last week is spent visiting the different bureaus of the State Board of Health,

and other state departments and institutions, among which is the U. S. Public Health Service Trachoma Hospital at Rolla.
M. T.

The Nurse in Education and Administration—The Mt. Sinai Hospital School of Nursing in New York City celebrated the golden anniversary of its founding at the New York Academy of Medicine, March 4. Laura Logan, Superintendent of Nurses of the Cook County Hospital, Chicago, a graduate of the Mt. Sinai School, was among the speakers. Her address follows in part:

The supply and demand study made by the Grading Committee for Schools of Nursing in 1928 showed that over 20 per cent of the nurses of the country were engaged in institutional nursing, over 20 per cent in public health nursing, and some 54 per cent in private duty nursing. It is known that only a small per cent of those doing institutional nursing are engaged as staff or bed-side nurses.

The grading study brought to light startling and significant facts with relation to the nurse in the field of nursing education. It showed that although there is an over supply of nurses in the field of private duty and with the present annual output of over 20,000 graduates this condition of unemployment is likely to grow worse—it proved that the supply of well prepared teachers, administrators, supervisors and head nurses for schools of nursing and for the field of public health is inadequate.

The recent White House Conference strikingly showed how important a part the nurse is expected to play in the nation's program for child health and development.

We have few figures to show that a well run nursing school is cheaper than the same service rendered by a well prepared paid graduate nurse personnel but we have figures to show that a good nursing service adequate in members is an economy to the hospital, while a poor nursing service is a direct liability—it shows up in the death rate, in the length of hospital stay, in the confidence and the good will of the community toward the hospital.

Society is changing its attitude toward the work of the nurse—this is measured by the rapidity with which universities are making a place for her preparation and by the importance of her place in the public health program. The nurse within the last 50 years has become a very important instrument or agent

of science in the application of its benefits to the race. It is therefore highly important that this agent, the nurse, be carefully selected, have a sound preparation in the sciences and the skills which are fundamental to good nursing. The administrators, supervisors, teachers, and head nurses in schools of nursing must not only be well prepared nurses but educated women skilled in the understanding of educational policies and of social and economic sciences, and so be able to incorporate into the training of the nurse that which will fit her especially in her professional service to society and also all that will fit her to live as a good citizen and to do her part in promoting a high quality of human life.

Endowments in universities are contributing to the preparation of professional workers no more important to social welfare than is the nurse. May we not expect from the community a recognition of need of endowment for schools of nursing and from the great body of medical men support and assistance in placing nursing on an academic and social basis comparable with other professions open to women?—

News Release of the United Hospital Fund of New York, Mar. 4, 1931.

These Would Raise the Standards
—The New York State Health Commission appointed by Governor Roosevelt in 1930 has presented to the Governor its preliminary report dealing mostly with health matters involving legislation. The following are recommendations in the report dealing specifically with public health nursing:

1. That county departments of health be developed throughout the state with a qualified supervising nurse under the direction of the health officer, who will teach, supervise and coördinate the work of all public health nurses employed in the county.

2. That the Department of Health be given facilities to continue and extend its efforts to promote the qualifications of public health nurses in the state.—

Health News, New York State Dept. of Health, VIII, 7: 25, 28 (Feb. 16), 1931.

EDUCATION AND PUBLICITY

EVART G. ROUTZAHN*

Montreal, September, 1931—Education and/or publicity will be well represented on the A. P. H. A. program. The Public Health Education Section hopes to welcome many who could not get to Minneapolis or Fort Worth. The date is so early in September that some may find it convenient to plan a vacation in Canada to end with a stop at Montreal.

"For The Good of The Order"—Quite apart from the program sessions it is hoped that several small groups would like to get together at luncheon or dinner to talk over "where are we going in popular health education?"

If you wish to put in a noon or early evening in such a discussion please write to the editor. Have you questions to raise as to the present or future status of health education?

Special: Cancer Education—Newspapers announce that through the will of Egbert C. Fuller a fund of \$1,500,000 will be devoted to research, care of patients, and the *education of the public as to the prevention and treatment of cancer*.

Health Education in a Survey Report—The Philadelphia Hospital and Health Survey includes 7 lines in the Appraisal of Public Health Activities; 5 pages on "Educational and In-

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

important public and college libraries.

Please check to see that the address is on lists for mailing all types of periodical or special material—reports, educational pamphlets, news, etc., etc.

HONORABLE MENTION

To National Tuberculosis Assn.: for giving date of publication on two pamphlets on school health topics.

MAGAZINE ARTICLES

Middletown, N. Y., March *Bulletin*, mentions that in *Delineator* for September Celia Caroline Cole gave some wild advice on the care of the eyes. Can you get some women's groups interested in health to write to the editor?

"The Care and Feeding of Adults," by Logan Clendening, M.D. *Collier's*. Mar. 21, 1931. "Get a doctor of your own." "How very delicate adults really are" . . . "watch a crowd around a soda fountain."

"Hard-boiled Mothers: Yesterday's Flapper as Today's Modern Parent," by Marian Castle. *Woman's Journal*, 171 Madison Ave., New York. Apr., 1931. 25 cents. For perplexed parents—and worrying elders.

"Hold Your Horsepower"—editorial. *Collier's*. Mar. 14, 1931. "Reckless driving in 1930."

"The Influenza of 1918," by W. A. Evans, M.D. *Liberty*. Feb. 7, 1931.

"Medicine and the Middle Class," by W. M. Johnson. *Atlantic*. Mar., 1931.

"Oh, Doctor!"—editorial. *Saturday Evening Post*. Mar. 21, 1931. Few medical men "have that peculiar gift for separating simple essentials from intricate surroundings" in presenting health information.

"Secretary Wilbur and the Cancer Cure," by M. A. Hallgren. *Nation*, 20 Vesey St., New York. Apr. 8, 1931. 15 cents. How a "cure" was patented.

"Specialists at Large," by D. D. Bromley; "The Cosmetic Urge," by

Jeanette Eaton. *Harper's*. Feb., 1931. "Tonsil Tricks," by Fassett Edwards, M.D. *Collier's*. Feb. 21, 1931. "Just what to do about tonsils baffles many of our best people."

EDUCATION—PUBLICITY

The Cancer Program in Massachusetts, by George H. Bigelow, M.D.—Committee on the Costs of Medical Care. Includes educational activities. *Free*.

"Health for Better Adventures," by Prof. C.-E. A. Winslow. *World's Health*. Oct.–Dec., 1930. Convention address to American Red Cross urging the need of wider development of Red Cross health program.

"Health Propaganda Methods," by Dr. John Macmillan. *Public Health*, London. Feb., 1931. Need for health education by health departments; evaluation of effective means.

"The Importance of Cancer Publicity," by Ella H. Rigney. 9-page reprint from *Hospital Social Service*. Description of nature, extent and results of publicity by New York City Cancer Committee, 34 East 79th St. *Free*.

"Methods and Aims of Popular Health Education in Germany," by Prof. Adam, secretary-general, Reich Committee on Popular Health Education. *World's Health*, 2, Avenue Velasquez, Paris, France. Oct.–Dec., 1930. 50 cents. Development and extent of popular and school health education.

"The Philosophy of Health Education in the Clinic," by Iago Galdston, M.D. *Hospital Social Service*, New York. Jan., 1931. For reprint, address author, New York Academy of Medicine. Read the paper for the philosophy. The application:

In a large number of our clinics a visiting patient is obliged to wait from 5 minutes to an hour before his turn comes. In the majority of clinics such a patient sits looking empty-eyed about him, or discussing his condition with his neighbor, or again, perhaps

reading a newspaper or a frayed magazine. How much better it were if the waiting patient could spend his time reviewing posters, graphs, charts and photographs, or looking at stereopticon views or daylight motion pictures. Instead of the frayed magazine, could we not supply him with attractive literature dealing with health? Could we not entertain him and render his wait less tiresome by showing him stereopticon views or motion pictures?

"Popular Education," by Florence B. Sherbon. *Eugenics*, New Haven, Conn. Jan., 1931. 30 cents. Why "propaganda" (objected to by Dr. Pearl) is needed for advance of eugenics.

"Summary of a Social Hygiene Survey of Washington, D. C.," by Walter Clarke. *Journal of Social Hygiene*, 450 7th Ave., New York. Feb., 1931. 35 cents. Under "Social Hygiene Education" a valuable review of activities in homes, public schools, churches, social agencies and adult clubs.

The Summary of Educational Methods in Mental Hygiene is being prepared for publication by National Committee for Mental Hygiene. An advance report on talks and lecture courses, in *Mental Hygiene Bulletin* (Jan.-Feb., 1931), names 22 books listed 4 or more times in reading lists given out by speakers. It is interesting that only one book was recommended as many as 12 times.

POSTERS

"Making Health Charts," by Pearl Turner. *Public Health*, Mich. Dept. of Health. Feb., 1931. "A chart is a sort of catalog or category—it is a collection of small pictures all pertaining to one subject"—such as "Foods Containing Iron." Working suggestions—but please delete "small" before "pictures." *Free*.

"Charts Make Facts Convincing," by Margaret Merwin and Helen Davis. *Public Health Nurse*, 450 7th Ave., New York. April, 1931. 35 cents (easy to borrow a copy in your city).

Here "charts" are diagrams and placard statements—not groups of "small pictures." Uses discussed: in reports and exhibits, for speeches, articles, letters, materials, lettering, titles and labels, reproduction of charts.

A "mother and baby" poster—actually a poster and not a placard—in color—sketch by Sundblom—19" x 25"—with these words in small letters at the bottom: "Compliments of Evaporated Milk Association." *Free*. Address: 203 N. Wabash Ave., Chicago.

Safety posters—some especially good—some not so good—are supplied by Employers' Mutual Liability Insurance Co., Wausau, Wis. *Free*.

Once a month a new health or safety poster is displayed in all Western Electric plants. Better than average quality. *Copies not available*.

Both above series of posters are about 9" x 12". Both groups will be shown at Montreal.

Those interested in the desirability of bill-board posters for health education will wish to see *Roadside Bulletin*, Natl. Council for Protection of Roadside Beauty, 119 E. 19th St., New York. *Free*.

ANSWERS

Asked for: "exhibits that could be used at state or county fairs—especially activity exhibits." *Answer:*

There are practically no readymade exhibits available through national or other organizations. One of the very few exceptions is the U. S. Children's Bureau, Washington, D. C., to which I suggest that you write.

Inquiry:

Our Association is planning a health exhibit at two of the fairs in the county this fall. I shall be glad of any suggestions for posters along health lines or any exhibit that would be attractive for this purpose. We are planning on three departments, we might call them. One each might be periodic health examinations; prenatal work, maternal and infancy. In the third division we might use some diphtheria prevention work, vaccination work and nutrition if our space is ample.

Answer:

The job of planning the exhibits—and the bigger job of presenting them to the fair visitors would be simplified if you could content yourself with but two or even one subject.

Why not make a big splash in one subject? Pick one of the seven you mention—one that you will emphasize especially this season, the one you can exhibit most effectively.

A list of poster sources is supplied by National Health Council, 450 7th Ave., New York, for 10 cents.

Reference to the newer posters will be found under Education and Publicity, in the monthly issues of the *American Journal of Public Health*.

Under the same heading, in various issues, the *Journal* offers many suggestions on making exhibits.

Inquiry:

The Tuberculosis and Public Health Society is now coöperating with the Medical Society in arranging health talks to be broadcast over our local station. I would appreciate it very much if you could give me some suggestions as to subjects that would be desirable in such a program.

Answer:

The best source of information regarding topics and prepared talks for radio use is the Education and Publicity Department in the *American Journal of Public Health*. I think you can do no better than to go through the files for several years back.

To which was added several specific sources already mentioned in this department.

TITLES AND PHRASES

Some of these titles may suggest new slants on old topics—new ways of saying old stuff.

"The Inside of Your Head"—or "Mental Hygiene?" Which article will get the more readers?

"Are Modern Parents Failures?"—*Hygeia*. "In defense of parents."

REPORTING

"Alaha from Phil Platt" is written on the cover of the report of Palama Settlement Work, Honolulu. Palama is somewhat like Henry Street Settlement in that it carries a city-wide nursing service; in addition it is the center for community health and recreation activities. Among interesting features of the report are: self-indexing (like unabridged dictionary); "Milestones": "For 33 years a center for free medical service to the poor"—"For 25 years provided a public health nursing service"—and so on. Probably copies on request.

A Chronological Report: Significant Events and Steps in the Organization and Progress of the Cattaraugus County and Syracuse Health Demonstrations—State Charities Aid Assn., 105 East 22d St., New York. Valuable document for students of these demonstrations.

A Day With The Visiting Nurse—Instructive Visiting Nurse Assn., Washington. A 9-fold folder—letter enclosure size. The story told in pictures with text and brief titles and plenty of white space. Dull finish paper is used. *4 cents for copy.*

Recent Progress in Health Organization in Honolulu, by Philip S. Platt, Palama Settlement, Honolulu. 8 pp. illus. *Free.*

Report of the Connecticut State Tuberculosis Commission—marked by the numerous page illustrations and the many pages of small type lists of contributions and services of various kinds.

Reporting within the family—and gleaned data from many sources is discussed in an especially helpful article—"Relating Hospital Service to Community Needs," by A. C. Philips and D. Dunker. *Trained Nurse*, 486 4th Ave., New York. Feb., 1931. *35 cents.* Many suggestions could apply to departments and other health agencies.

"Saving Life by Preventing Illness"—happy title—is "A Review of the work of the Tuberculosis and Health Society of Detroit and Wayne County for the year 1930"—51 Warren Ave., West, Detroit, 8 pp.—3¼" x 9"—rough paper—large type—readable—no statistical tables. *Copy free.*

The Year's Progress—Philadelphia Health Council and Tuberculosis Committee—a 12-page narrative report—several illustrations—1 page financial statement including functional classification of expenditures. *Free.*

CONTESTS

Scribner's Magazine, New York, offers prizes of \$1,000 and \$500 for narratives of 2,500 to 6,000 words. Closes June 20, 1931. "The stories must relate to some phase of American life."

Public health in some of its aspects offers rich source material for the writer.

The Hospital Committee, Raleigh Woman's Club, offers prizes for best papers by high school students on "The Value of a Hospital to a Community." Details in *Health Bulletin*, North Carolina State Board of Health. Apr., 1931. *Free.* Local clubs might sponsor essay contests on other health subjects.

Year after year the Association of Infant Welfare and Maternity Centres, London, conducts a group of contests for children, mothers and communities. A health talk by health workers was judged by medical men and by a group of mothers. Address: 117, Piccadilly, London, W. I., England.

The 10th annual health poster contest is being conducted by the Anti-Tuberculosis Society of Schuylkill County, Pa. For high school, 7th and 8th grade students.

Two contests—training student essays, and play or pageant writing—are being conducted by American Nurses' Assn., 450 7th Ave., New York.

VOLUNTEERS

"High Voltage Volunteers—How to Get Them—Train Them—Keep Them," by J. A. Wolf. *Survey*. Nov. 15, 1930. "Only a fraction of the work in the vast field . . . could be done without volunteers."

"The Volunteer of the Junior League and Public Health Nursing"—"County Volunteer Service"—"The New Volunteer." 3 articles on the great untapped resource for public health work. *Public Health Nurse*. Mar., 1931.

NEW

Bulletin, Pennsylvania Heart Assn., Philadelphia.

American Journal of Orthopsychiatry, 145 E. 57th St., New York.

BOOKS AND REPORTS

Child Health—By *Norma Selbert, R.N.* Philadelphia: Saunders, 1931. 239 pp. Price, \$1.60.

This volume is a companion to the author's book *Home Care of the Sick*, and is intended primarily for courses in child hygiene and in adult education in child care, which are now being introduced in a number of our universities. The book is in the form of a compendium of information pertaining to child health and covers the period from conception through school age. It is written with a sketchy, easy style in non-technical language.

Mrs. Selbert has drawn exhaustively from the literature on child hygiene and practically every page contains one or more references. The various factors concerning child health are boiled down to lowest terms and in some places are stated with dogmatic assurance. The whole book is non-controversial even in those parts where a question might be raised regarding lack of definite scientific information.

The book opens with a bird's-eye view of the evolution of child health work, especially in the United States. The second chapter, taking up problems affecting the growth of children, sets forth briefly some of the factors which condition children's growth. An attempt is made to state the modern concepts regarding parental education and the various psychological elements which enter into relationships between parent and child. While a considerable amount of information is assembled within small compass, it seems that could a greater amount of space be given to the subject, better proportions would result.

The chapters on prenatal care and

the natal period conform closely to other literature on this subject. The procedures on the whole are standard ones. The nursery school movement is traced briefly and the development of the nursery school in America is outlined. The chapter on the school child and the adolescent presents material gleaned from diverse sources. The effect of child labor on the child is treated in a very concise but satisfactory manner, and a chapter devoted to the use of leisure time and health camps is very applicable at present when we are seeking to build better health standards for summer camps.

The book contains a wealth of illustrations bearing upon the various subjects under consideration. In other words, this book is a condensation of present knowledge on child hygiene, written in non-technical language, and accessible for ready reference. It does not pretend to offer original investigation or take up controversial matters. It should be of value in conducting informal health education, and serve as a reference book for classes in child hygiene.

RICHARD A. BOLT

Proceedings of the Fourth Annual Conference Maryland Water and Sewerage Association, Hagerstown, Maryland, May 13 and 14, 1930. 120 pp.

This publication, which is prepared in good style and includes a number of interesting illustrations, covers a variety of subjects. Garbage and refuse collection and the reclamation and disposal of trash; sewage treatment problems, and various phases of water procurement and purification are covered.

ARTHUR P. MILLER

Nervenärztliche Gutachtertätigkeit.
Dargestellt für die praktizierenden
Ärzte—By Dr. Max Scrog (Leipzig,
Georg Thieme), 1931. 60 pp. Price,
M. 3.60.

This booklet treats mainly of neuroses due to trauma of the peripheral and central nervous system. It discusses the basic principles involved in the handling of such cases, and notes their relations to accident and health insurance. Numerous examples drawn from a wide experience clarify and illuminate the discussion. Cases arising in the course of military service in the World War are treated in a special chapter. The psychiatric aspects of the subject are only briefly discussed. C. A. KOFORD

Therapeutic Uses of Infra-red Rays
—By W. Annandale Troup, M.C.,
M.B., Ch.B. London: The Actinic
Press, Ltd., 1930. Price in U. S. A.,
\$1.50.

This is said to be the first book published in Britain devoted specifically to therapeutic use of infra-red rays. It appears to be based upon the experience of the author in his own practice but includes frequent references to the rather scarce literature on this application of heliotherapy.

Certain statements which are unsupported by evidence or reference are likely to be questioned by one conversant with the general laws of optical physics, for instance, "The depressing effects of the tropics . . . have been attributed to infra-red rays . . . the ultra-violet rays are practically entirely absorbed by water vapor. . . ." It is generally accepted that water *per se* does not offer serious interference with ultra-violet transmission, and also that energy from $\lambda 14000$ to $\lambda 80000$ is practically entirely absorbed by even 1 inch of water.

The suggestions made of the mutual assistance or interference of ultra-violet and infra-red seem to have an empirical

basis not entirely in accord with all published data.

In the main it appears that the scientific facts are soundly set forth. As to therapeutic practices, these are to be judged in the light of results obtained until more basic knowledge of fundamental facts as to the cause of these can be worked out.

The book should serve as a useful guide to the practitioner, who will, in all probability, pursue a course of trial and observation, rather than follow literally exact procedures recommended.

Quoting from the foreword by Sir William Wilcox, ". . . the use of infra-red irradiation by medical practitioners will prove a really useful . . . form of clinical research."

JOHN W. M. BUNKER

Handbuch der Tropenkrankheiten—
herausgegeben von Prof. Dr. Karl
Mense. Ed. 3 (Leipzig, Verlag von
J. A. Barth), Johann Ambrosius
Barth, Leipzig C 1, Germany, 1929.
Teil 1, 846 pp., 362 figs.; Teil 2, 847–
1418 pp., figs. 363–556. Rm. 90.—

The fifth volume of this well known and much appreciated treatise on tropical medicine has now been published. It is of prime interest, because of the inclusion of helminth diseases, relapsing fever, and other spirochetoses, Chagas' disease, and yellow fever, and the protozoan parasites of the blood of vertebrates.

The general section deals with the distribution and favoring conditions for the various helminth infections of man, such as ascariasis, oxyuriasis, trichocephaliasis, ankylostomiasis, dracontiasis, filariasis, trichinosis, schistosomiasis, and the principal cestodes of man. Accessory and intermediate hosts, and vectors of the helminths of man, the distribution throughout the world and among different peoples, of the parasitic worms, the clinical signs of helminth infection, the action of the worms on the

host, helminth plagues and diseases, the detection and differentiation of worm infections by fecal examination and culture, by the radioscope, and by immune reactions, and the treatment and prevention of helminth diseases are summarized. In the special section each important parasite receives detailed discussion.

The spirochetoses receive an extended discussion of 250 pages at the hand of Dr. H. Ruge of Hamburg.

Dr. Carlos Chagas of Rio Janeiro, assisted by Dr. Villela and Dr. Rocha-Lima, brings the subject of American trypanosomiasis up to date, noting especially the cardiac and neurotropic aspects of the infection and the disease. The armadillo is the reservoir mammal and *Triatoma*, a kissing bug, the insect vector.

The chapter on yellow fever is of especial interest to American readers, not only because of the repeated invasions of "Yellow Jack" into the United States, and because of the extensive quarantine system in vogue against it, but primarily because of the contributions of the late Dr. Noguchi to its solution. The bibliography contains 33 articles from his pen. They cite the difficulties in the way of accepting Noguchi's *Leptospira icteroides* as the etiological factor, and the conclusion is reached that the Brazilian and the African yellow fevers are identical. Investigators are not absolved from continuing the Noguchi hypothesis within the scope of further investigation, though they appear to be unconvinced of its correctness.

Part two of the fifth volume of this monumental treatise on tropical medicine is given over wholly to the protozoan parasites of the blood of vertebrates. The treatment of malaria and of the species of *Plasmodium* afflicting man is found elsewhere in the third volume. The species of this genus occurring in other vertebrates are, however,

included here with the other Hemosporidia.

Professor R. Kudicke of Canton, China, is the author of this section of the work, with the exception of the part dealing with African sleeping sickness, which is written by Professor Carl Mense, the general editor of the entire work.

The invasion of the blood stream by the Protozoa occurs throughout all of the classes of vertebrates, but is best known among land vertebrates, perhaps in part because of ecological considerations, but on biological grounds because of the access of blood-feeding Arthropoda. Thus in this phylum several families, many genera, and still more species, are vectors of blood flagellates, or Sporozoa. Thus the mosquitoes (*Culicidae*) carry *Plasmodium*, *Laverania*, *Proteosoma*, and *Trypanosoma*; the horse flies (*Tabanidae*) and tsetse flies (*Glossina*) carry *Trypanosoma*; louse flies (*Hippoboscidae*) carry *Trypanosoma*, *Hemoproteus*, and *Leucocytozoon*; the sand flies (*Phlebotomus*) carry *Leishmania*; the fleas (*Aphaniptera*) carry *Trypanosoma*, and the Hemiptera (*Triatoma* or kissing bugs) carry *Trypanosoma* and *Schizotrypanum*. Among the Arachnoidea the ticks (*Ixodidae*) carry *Babesia*, *Nuttallia*, *Theileria*, and *Hepatozoon*; and the mites (*Gamasidae*) carry *Karyolysus*, *Schellackia*, and *Hepatozoon*. Among fishes and amphibians the leeches are vectors of *Trypanosoma*, *Trypanoplasma*, and *Hemogregarina*.

This imposing list is indicative of the extent to which the evolution of blood feeding insects, arachnoids, and leeches has been attended by the evolution of protozoan blood parasites. The presence of flagellate and sporozoan parasites in the digestive tracts of non-hematophagous insects, arachnoids, and leeches suggests the derivation of the invaders of the blood stream of vertebrates from the less specialized parasites

in the digestive tract of these invertebrate hosts.

Dr. Kudicke writes of the blood flagellates. He gives an extended account of the pathogenic and non-pathogenic trypanosomes of mammals. The author is conservative in most matters of terminology and nomenclature. Thus he retains blepharoplast for the structure in the Trypanosomidae which most protozoologists, following the interpretation of the reviewer, are now calling the parabasal body. He also adheres to the old name *Lamblia* instead of *Giardia*, which clearly has nomenclatural priority and now has wide usage in all leading treatises on protozoology.

The subject of African human sleeping sickness is treated by Dr. Mense. He discusses the remarkable history of this dread plague of tropical Africa, tracing it from the Hebrew records to its present flare along streams and shores of lakes from Senegal into Angola, and from the Soudan into Rhodesia. It varies considerably in virulence, in intensity of infection, and in the resulting mortality. Treatments by arsenicals, including the trypanosamide and the German 205, or germanin, are not certainly successful and often fail in advanced cases of the disease. But the victim of this dread infection need not in the early stage, as formerly, look forward to a fatal termination.

The author holds as inconclusive the evidence that the wild game of Africa is widely infected with the human trypanosome, and refrains from advising its extermination as a protection to man in endemic areas of trypanosomiasis.

The volume is notable in scope and treatment, and maintains the well known high standard of illustration, documentation, editorial coordination, and scholarly thoroughness which has always characterized this work under the capable leadership of the veteran

investigator of tropical diseases, Professor Dr. Carl Mense. It is a fine contribution to this active field of medical investigation.

C. A. KOFOID

Personal and Public Health—By Burkard, Chambers and Maroney. New York: Lyons and Carnahan, 1930. 516 pp. Price, \$1.08.

This text, intended for junior high schools, uses the very logical but rarely found method of presenting the closely related personal health facts in closely related style. This is the outstandingly good feature of the book. As a result the chapter on The Muscular System, for example, includes the related facts of anatomy, physiology, nutrition, general hygiene, safety, and first aid; that on Teeth, their structure and development, the importance of diet in relation to fine sound teeth, personal and dental care; and teeth as focuses of infection. The use of more than 4 pages for presenting various methods for brushing the teeth rather spoils the emphasis on the relation of nutrition to fine teeth, and raises a question as to the confidence of the authors in the effectiveness of the health habit material presented in the first books of their series.

The community health facts are presented in such a way that the more abstract ones relating to federal and state precede the more concrete home, school, and local community health facts. The suggestions for Health Habit Formation are practical but any challenge to the pupils will have to be supplied by the teacher or the children themselves.

The mechanics of the book leave something to be desired from a health standpoint since the various sizes of type break up the pages in a way to irritate even the untrained eyes of a child. The English also leaves something to be desired in that the almost constant use of simple sentences is

monotonous; for example, "The arms and legs are joined so that they act as levers," and "There are four curves in the spinal column as viewed from the side."

MARY L. HAHN

Health and Life—Consultations with Eminent Doctors. Edited by Morris Fishbein, M.D. Chicago: Manning Publ. Co., 1931. Set of 8 volumes. Price, \$4.00, \$.50 each.

Here is a new series of attractive little books on health, written by eminent physicians in conversational style so as to appeal to a wide popular audience. These should prove helpful on the table in the waiting room of the busy practitioner. They should also find a place in the hands of teachers, nurses, and health educators.

They will do much to strengthen the growing opinion that physicians are instructors in health as well as in curing disease, and that they are glad to take the public into their confidence on all important matters concerning personal hygiene.

Incidentally, these volumes will act as an antidote to much of the hurried, ill-digested and erroneous material put out in the name of health education at the present time.

It is not possible to give consideration to each individual volume. The soundness of the content is guaranteed by the reliability of the authors of each chapter.

RICHARD A. BOLT

An Exhibition Handbook—By Randall D. Warden. New York: Barnes, 1929. 107 pp. Price, \$1.00.

The first thing to recommend this book is its practical usefulness to any department of physical education. The public is usually entertained by well presented exhibitions of this type. The Handbook sets forth a program for such an exhibition together with detailed directions for putting it on. In addition to being an interesting program it will

give any school patron a very good idea of the sort of work the department is doing. Free exercises, those demanding a fair equipment of apparatus, tumbling, and dancing, make it possible to give every group a chance to display its proficiency. The last pages are given over to an out-of-door festival with full directions for its presentation.

LENNA L. MEANES

Wholesome Living Series: Health and Happiness; Health and the Rules of the Game; Health and Control; Health and Service—By Jesse Feiring Williams and Theresa Dansdill.

Health and Ideals—By Jesse Feiring Williams. Boston: Benj. H. Sanborn & Co., 1930–1931. Price, \$.64, \$.64, \$.68, \$.72, and \$.80.

In this series for textbook use in public schools from the 3d grade up to and through junior high, the subject of health, as the title indicates, is treated as a trinity of physical, mental, and social well-being. No part of this trinity can be at its best without the best of health in all three. Health education therefore becomes, not just a matter of instruction in hygiene—or not of that plus instruction in public health measures—but rather a matter of correlating health with all life. The rules of the health game are made imperative in playing the whole game of living with one's group—living it as the boy or girl wants to live it as a well trained, fit member, able to take his own part, able now and then to lead.

The first of the series—for use in the 3d grade—called *Health and Happiness*, and the second—*Health and the Rules of the Game*—for 4th grade, are both collections of attractive stories for children, each introducing some simple but vital phase of health activity and nailing the lesson down by questions supposed to be asked by a child of the story and really asked by a group of

children in trying out the material for use in the book. These two of the five are illustrated in color by Alexander Key.

Health and Control and *Health and Service* follow for the 5th and 6th grades. These are more formal in plan, taking on chapters and general textbook arrangement, but show a skillful handling so that facts in health living are made live, vital, to be used in making oneself a desirable member of a group. Illustrated in black and white.

Health and Ideals is planned as a text for 7th and 8th grades; particularly its manner of presenting the physiological material—really very comprehensive and technical—is adapted to appeal to the motives common to adolescents, ranking high among which is the desire to be well trained like the athlete of the school, to be a good fellow in playing the game, and to be fit to meet any great adventure that may come along. Technical drawings by T. M. Stell, others by Alexander Key.

LENNA L. MEANES

Practical Massage and Corrective Exercises with Applied Anatomy
—By *Hartvig Nissen*. Boston: Davis, 1929. 271 pp. Price, \$2.50.

As student, teacher, and masseur from the Swedish school, Nissen brings his experience and knowledge to the public in a clean-cut, practical fashion, which puts massage in its proper place in relation to all exercise. The author gives us the why and the what and the result of manipulations in the first section of his book. He follows by doing the same for corrective exercises. While by no means claiming that exercise is a cure for all ills, he does, in the last division, make an intelligent claim for it in many instances. The book is blessed with a very comprehensive table of contents and an adequate index. In addition it is well set-up so as to make its reading attractive. The 72 illustrations

—half tones and line engravings—are excellent.

LENNA L. MEANES

Margarine as a Butter Substitute—
By *Katharine Snodgrass*. Stanford University, Calif.: Food Research Institute, 1930. Price, \$3.00.

Prepared under the Directors of the Food Research Institute, who have also contributed certain sections to it, this volume is an illuminating study of oleo-margarine from its introduction to the present. The processes of manufacture are described, and the materials used mentioned and discussed. Naturally, developments in the butter industry had also to find a place, and several chapters are given to a consideration of the butter and margarine markets. The various vegetable oils, their sources, production, purification, and uses, come in for treatment. The economics of the situation are considered, and some 9 chapters are given to legislative enactments, in addition to which there are 2 appendixes which give summaries of federal and state legislation.

The volume strikes us as being an impartial and comprehensive study. This feature is brought out particularly in "Concluding Remarks," where the material is summed up under 2 heads, for margarine on the one hand, and butter on the other. It is stated clearly that there is truth in the claims of both sides. Involved in the controversy, there is also the question of vegetable oils, some, such as cotton seed, peanut and corn, produced in this country, some in our dependencies, like the Philippines, and some in foreign lands. The economic aspect is given full attention. One must read the book to get a clear idea of the complexity of the situation, and the various interests which are involved. The only persons who seem so far to have been left out of consideration are the consumers, a fact upon which the author comments.

It seems clear from the text that politics has played a large part in the controversy, and it will probably come as a surprise to many to be told that the question of independence of the Philippine Islands is involved, since at present they are able to import coconut oil free of duty, in competition with American producers who refine the oil from copra.

There are numerous charts and tables taken from governmental sources, showing relative consumption, production,

export, prices, number of milch cows, and other data bearing on the matter.

The book can be thoroughly commended to all who are interested in this question, which has been discussed for many years, and has given rise to much bitterness.

The printing and make-up of the book are excellent. The author has had assistance of the Directors of the Food Research Institute, as well as a number of experts in various parts of the country. M. P. RAVENEL

HEALTH DEPARTMENT AND OTHER REPORTS

IRA V. HISCOCK

Racine, Wis.—The 1930 report for this city of 67,515 opens with a graphic presentation of population, birth and death rate trends, followed by an organization chart of relationships of official and voluntary health activities. The central family file inaugurated by the health department in January, 1929, contains almost 13,000 records, including most of the families in the city. An infant mortality rate of 39.4 and a neonatal rate of 27.2 are recorded. The tuberculosis rate was 57.7 and the general death rate 9.8. The 1931 budget was \$44,045.

Through the coöperation of various organizations, a preschool campaign resulted in the examination of 796 children, or 49 per cent of the entering group. Radio talks given by the health commissioner numbered 41. Pamphlets distributed numbered 74,719. The total number of children receiving toxin-antitoxin was 1,871, of whom 69.5 per cent were less than 5 years of age. During a 5-year campaign, 11,315 children have been thus protected. Of 5,143 children given subsequent Schick tests, 95 per cent gave negative reactions. As usual, this report abounds in enlightening statistical tables and interesting descriptive text.

Henderson County, Ky.—The personnel of the full-time unit consists of a staff of 5, to serve an area of 450 square miles with a population of 26,600 in 1930. There are 25 practising physicians in the county, 18 of whom reside at the county seat. An estimate by the County Farm Agent of the effect of the drought on crops was as follows: about 20 per cent reduction in the tobacco acreage, 70 per cent damage to corn crop, and 75 per cent damage to hay and pastures. The Public Welfare Association of Henderson received

nearly 3 times as many applications for assistance in 1930 as in 1929.

There were 515 live births in the county in 1930, 82 being colored. A death rate of 12.7 is reported, based on 336 deaths. An infant mortality rate of 68 is recorded. There were 24 deaths from tuberculosis. Throughout the year, popular education through talks, bulletins and personal interviews was developed in tuberculosis control. A sign board 6' x 8' was constructed by the health department and placed in the court house yard, bearing in large print a message of warning against tuberculosis. From seal sale funds a tuberculosis hut, 8' x 10', was built for a male tuberculosis patient. Photographs of these activities illustrate the report.

The major part of the health department work was devoted to school hygiene. A Blue Ribbon campaign was inaugurated, culminating in a May Day celebration. During the year 1,921 physical defects of school children were known to have been corrected.

Pennsylvania—The 1929 Year Book indicates for the state a birth rate of 19.1 and a death rate of 11.9. The typhoid death rate of 1928 was 2.0, indicating a continuous decrease over a period of years due in large measure to the safeguarding of public water and milk supplies. The diphtheria rate in 1929 of 6.8 is the lowest recorded. The tuberculosis death rate was 63, a reduction from 151 in 1906. Detailed statistical tables are submitted by counties, and several graphs indicate mortality trends.

A system of cross-checking of fatal reportable diseases begun in 1926 led to measures which stimulated the reporting of cases. During the past 8 years the department has supplied sufficient

diphtheria toxin-antitoxin to protect over 800,000 children. "Pennsylvania has a vaccinated population, thanks to the beneficent action of the Legislature in passing a law requiring the vaccination of school children."

The bureau of milk control promotes the distribution of a clean, safe public supply and an increase in milk consumption. State department activities include farm inspections (2,020), plant inspections (483), and special tests. The state is divided into 8 districts for supervision purposes and the control officers live in their respective areas.

The bureau of child health, organized in 1923, brings under one administrative head the preschool, school, and dental work of the department. The school division reports 269,161 pupils examined and 199,821 pupils advised on treatment during the last school year. During the summer months, motor units were sent into the rural sections for the examination of infants and preschool children.

Detroit, Mich.—The January issue of *City Health* is devoted to the annual report of 99 pages under the title "1930 Our Healthiest Year." Excellent graphs, photographs and statistical tables accompany enlightening descriptive text.

Among the outstanding points of health interest listed are a death rate of 9.2, an infant mortality rate of 65.3 as compared with 104.2 in 1920, an increase in hospital beds for tuberculosis to 2,088, a tuberculosis death rate of 82.5, the immunization of 57,000 children against diphtheria by the private physicians of the city, and a reduction in the diphtheria death rate to 10.9, or one-half of the 1929 rate. A series of weekly clinical conferences on communicable diseases was held at the Herman Kiefer Hospital under the auspices of the public health committee of the Wayne County Medical Society.

The average attendance exceeded 225 physicians.

The department of health personnel of 1,834 is given in a classified table according to functions. A financial tabulation shows gross expenditures of \$3,962,870, with credits of \$1,825,000. Preventive medical service expenditures amounted to \$1,585,230 in this city of 1,585,653 population.

The milk inspection division pictures the monthly milk supply in terms of a lake of milk $2\frac{1}{2}$ feet deep, $\frac{1}{2}$ mile long, and over 100 yards wide, weighing over 30 million pounds. Milk supervision is organized from the point of production to the time of delivery. There are 14,600 farms, 30 pasteurizing plants, the former receiving 17,880 inspections and the latter 4,473 inspections during the year.

All food handlers must possess an annual card issued by the department of health, indicating that they have had, during the year, a complete physical examination. Such examination may be made by any reputable licensed physician or by the department. As a means of making the physical examination of more personal value to the individual, all food handlers appearing for examination at clinic are given elementary talks on personal hygiene while they are waiting for examination. In 1930, 13,818 examinations were given, of which 8,448 were by private physicians.

The child health service of the department of health was previously reviewed in this column. The Board of Health has described the educational functions of the public health nurse as follows: (a) prevention of illness; (b) measures to be carried out to secure the alleviation of sickness; (c) social service matters which involve proper hygiene in the home—this may involve such budgetary management of income that the nutritional requirements of the family may be adequate; (d) child hygiene; (e)

applied psychology; (f) a knowledge of welfare agencies which are available, together with the aid they can render; (g) a sound theory and practice of rest, exercise, food, raiment, cleanliness, and how inciting agents are spread; (h) laws, regulations, and procedures for preserving the public health. With these functions in mind, the board has set up qualifications for the nurses of the department.

Winona, Minn.—Pasteurization is required of all milk sold in this city. Coöperation between milk producers, distributors, and the department of health has resulted in the stabilization of milk prices. The producers receive 60 per cent of the retail price and the distributors 40 per cent. Milk purchased from the producers is on a flat rate, the minimum butter fat content being 3.5 per cent. The consumer pays 11 cents a quart for standard milk equivalent to Grade A pasteurized, which is produced from cows tuberculin tested annually under the federal and state accredited herd plan and physically examined quarterly.

This city, with a population of 35,144, reports for 1930, 241 deaths, 429 births (265 in hospital, 15 attended by midwives), with 16 deaths under 1 year of age. The average length of life of residents, excluding infant deaths, was 60 years. There were 7 deaths from tuberculosis, with no deaths from diphtheria. Attendance at infant welfare clinics numbered 1,522, while home visits totalled 1,678. This report of 22 pages is written in a popular style worthy of commendation.

Palo Alto, Calif.—Palo Alto's annual report for 1930 was off the press on February 28—an excellent record. To be of greatest usefulness, early publication of annual reports is desirable. On the basis of a population of 13,800, a death rate of 9.6 is recorded. Eight

of the 15 deaths from tuberculosis recorded were of persons over 63 years of age. The infant mortality rate was 39.2, as compared with 41.3 for the preceding 10-year period. There were 37.6 cases of communicable diseases reported per 1,000 population.

Milk consumption has reached 1.2 pints per capita. Two surprise milk tests were made of the local milk supply by representatives of the State Department of Agriculture, and a general average score of 97.8 was obtained. Palo Alto received honorable mention in the 1929 health conservation contest of the U. S. Chamber of Commerce. There have been no deaths in the city from diphtheria since 1921. Active immunization was carried on as in former years, 420 children having been protected by local physicians and the health department.

Steubenville, O.—A vaccination campaign in 1930 resulted in the vaccination of 1,156 persons, including 29 adults. A subsequent survey showed 66 per cent of the 7,360 school children protected. There was 1 case of small-pox during the year. At the preschool clinic there was an attendance of 167. Of 2,766 school children Schick tested, 1,128 were found to be susceptible to diphtheria and 500 of these were immunized. The immunization campaigns were conducted with the coöperation of the local medical association.

The milk supply is obtained from 490 dairy farms in 5 adjoining counties. Pasteurization safeguards 85 per cent of the supply. Inspections are made of farms and pasteurizing plants. A modern milk ordinance was passed in 1929.

Vancouver (B. C.) Hospital Survey—A comprehensive report has been issued by the Vancouver hospital survey commission upon the hospital situation of greater Vancouver, conducted under the auspices of a joint committee

of the city council, the hospital board of directors, and the provincial government of British Columbia. The report is of 220 pages with 8 chapters and an appendix. Several charts and a topographical map add interest to the report, which deals with public health and welfare activities, as well as hospitals.

A metropolitan hospital plan is suggested, which includes the organization of a central laboratory for all institutions, with a small subsidiary laboratory in each hospital. It is suggested that the laboratory work of the health department be conducted in this central laboratory as at present. The commission favored the complete separation of all medical functions from the city relief department and their transfer to the outpatient department of the general hospital. It further suggests that the relief department under the direction of an experienced sociologist, confine its activities to material relief, unemployment, and community sociological projects.

A staff qualifications committee is proposed as an aid in selecting competent physicians for the hospitals. Two complete but separate attending staffs are suggested, each serving for a period of 6 months. By this time, it would be possible to compare each department with the corresponding department on the other service; it would also offer a wider opportunity to the medical profession, and the burden of charity work would not fall too heavily upon the shoulders of a small group.

It is suggested that private hospitals be placed under the inspectorial super-

vision of a Metropolitan Hospital Board, and that all future expansion programs be subject to the approval of that body. It is also recommended that the licensing of private, commercial hospitals be delegated to the proposed Director General of Hospitals of the Metropolitan Board. Fundamental standards for the conduct of an outpatient department are outlined. Emphasis is placed upon the need for a first class social service department staffed with experienced and well trained workers. A new institution is suggested for the care of chronic and convalescent cases.

Iowa—The biennial report for the period ending June 30, 1930, shows that the state-wide diphtheria immunization campaign has resulted in the protection of about two-thirds of the school children. Credit is given to the protection thus conferred for the reduction in deaths from a yearly average of 242 for the period preceding the campaign (1923) to 34 for the year 1929. There were 4,969 cases of smallpox reported, causing a calculated loss of time through quarantine of 382 years. The tuberculosis death rate in 1929 was 33. The epidemiologist's report contains a detailed account of severe epidemiological investigations of interest.

Considerable public health education work has been done. More than 200 letters and 2,500 pieces of second class mail leave the department daily, and a weekly health message on timely subjects is published. The health message topics are widely copied by newspapers throughout the state.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH. D.

Antiseptic Standards—Justly critical of the old methods of evaluating antiseptics, a new and complete survey of antiseptic qualities is advocated.

ALLEN, A. W., and WRIGHT, I. S. Determination of the Value of Antiseptics, *J. A. M. A.*, 96, 12: 920 (Mar. 21), 1931.

Coal Miners' Lungs—A radiographic study of industrially healthy miners reveals extensive lung alterations which represent a definite impairment of lung structure and function, yet are consistent with working health.

ANON. Coal Miners' Lungs, *J. Indust. Hyg.*, 13, 1: 19 (Jan.), 1931.

Public Health Law Fundamentals—Adequately described in the title. Good for the soul of the law enforcing officer.

BAUMAN, J. E. The Fundamentals of Public Health Law, *Pub. Health Rep.*, 46, 12: 631 (Mar. 20), 1931.

National Diets—This scholarly dissertation on diet goes deeper than calories of carbohydrates and proteins and considers the more fundamental and potent factors that influence the national dietary.

CATHCART, E. P. The Foundations of a National Diet, *Med. Off.*, 45, 12: 131 (Mar. 21), 1931.

The Future Physician—"Within certain limits, therefore, the physician of the future will be able to control the growth of the body and the development of the mind. He will acquire such a knowledge of biochemical and biophysical processes that he will be able to guide his fellow men as an engineer of living processes."

CRILE, G. W. The Medicine of the Future,

New York State J. Med., 31, 5: 272 (Mar. 1), 1931.

Tolerance to Staphylococcus "Poisoning"—Human subjects fed increasing doses of staphylococcus filtrates developed some tolerance to "food poisoning" produced by the strain.

DACK, G. M. Attempts to Immunize Human Volunteers with Staphylococcus Filtrates that are Toxic to Man when Swallowed, *J. Prev. Med.*, 5, 2: 151 (Mar.), 1931.

Progress of Clinics—The tendency of clinics to expand in number and scope and to become centers of medical service rather than charitable enterprises leaves many problems for the medical profession to solve. The discussion of these problems becomes a most interesting paper.

DAVIS, M. M. What the Public Has a Right to Expect of Clinics, *New Eng. J. Med.*, 204, 12: 604 (Mar. 19), 1931.

Fostering the Unfit?—An eloquent answer to the dimwit who cries out against our modern health measures on the ground that we are fostering the weakling.

EMERSON, H. Are We Fostering the Unfit? *Survey Graphic*, 46, 1: 49 (Apr.), 1931.

White House Conference Continued—The final session of the President's Conference on Child Health so rich in fact finding, but about which there was so little public acclaim, is briefly summarized.

EMERSON, H. The Child Takes the Lead, *Survey*, 65, 12: 649 (Mar. 15), 1931.

Epidemic Poliomyelitis—In readily understandable form, this excellent statement of the present status of our knowl-

edge of poliomyelitis is a good example of "how it should be told."

HEKTOEN, L. Infantile Paralysis, *Pub. Health Nurse*, 23, 3: 114 (Mar.), 1931.

Tonsils, Adenoids and Infections—A 10-year study of 4,400 controlled children indicates that removal of tonsils and adenoids favorably influences the incidence of colds, sore throats, rheumatic fever, diphtheria, scarlet fever, nephritis. Chorea, measles, laryngitis and tuberculosis seemed to be improved to a slight degree. But bronchitis, pneumonia and sinusitis were influenced unfavorably.

KAISER, A. D. The Relation of Tonsils and Adenoids to Infections in Children, *Am. J. Dis. Child.*, 41, 3: 568 (Mar.), 1931.

Telling Dear Public—One of the best examples we have seen of a story about health work by a practising sanitarian. If more of them would go and do likewise, many more people would know what public health really is.

LAYBOURN, R. L. Laboratory Specimens, *Survey Graphic*, 65, 11: 607 (Mar. 1), 1931.

State Health Survey—This survey of the health administration needs of Oklahoma contains much that may be applied to state administration generally.

McLAUGHLIN, A. J. A Public Health Survey of Oklahoma, *Pub. Health Rep.*, 46, 11: 575 (Mar. 13), 1931.

Tuberculosis in Children—A plea for early institutional treatment to check tuberculosis in children, to prevent the greater part of the deaths from the disease in adult life.

McPHERDAN, F. M. Some Aspects of Tuberculosis in Children, *Brit. M. J.* 3660: 342 (Feb. 28), 1931.

Venereal Disease Reporting—Approximately 1,000 physicians, or less than a third of the number who saw venereal disease patients, were responsi-

ble (with public clinics) for more than 11,000 Massachusetts case reports in 1930. The study of these reports leads to interesting conclusions.

NELSON, N. A., and SCAMMAN, C. L. Gonorrhea and Syphilis in Massachusetts in 1930, *New Eng. J. Med.*, 204, 13: 637 (Mar. 26), 1931.

Diphtheria Toxoid—This description of the preparation and dosage of toxoid explains the probable reason for some of the conflicting reports of early experience with the product which will eventually replace toxin-antitoxin mixture for routine immunization of small children against diphtheria.

POVITZKI, O. R., *et al.* Diphtheria Toxoid, Preparation and Dosage, *J. Immunol.*, 20, 3: 247 (Mar.), 1931.

Diagnosis of Tuberculosis—Of a group of persons applying for employment, 1.2 per cent had X-ray evidence of tuberculosis without other physical signs. More than half showed progressive disease within the year. This is a significant finding to be considered by health examination propagandists.

REID, A. C. X-ray Tuberculosis in Apparently Healthy Individuals, *New York State J. Med.*, 31, 6: 337 (Mar. 15), 1931.

Diphtheria Mortality—Statistical evidence of what is very generally accepted: mortality increases with delay in the administration of antitoxin; rural mortality rates exceed urban, regardless of method of treatment; mortality expectancy decreases with age.

STEVENS, I. M. An Analysis of 3,122 Diphtheria Case Histories, *Am. J. Hyg.*, 13, 2: 392 (Mar.), 1931.

Measles Diagnosis—Three aspects of measles control are discussed: the priority of fever in symptomatology; the importance of eye signs in early diagnosis; and the necessity of individual isolation.

STIMSON, P. M. Important Aspects of

Measles, *New York State J. Med.*, 31, 6: 352 (Mar. 15), 1931.

Encephalitis Following Vaccination—Three cases of encephalitis following anti-smallpox vaccination are presented in a discussion of the differences between this condition, encephalitis lethargica, and tetanus.

VIETS, H. R., and WARREN, S. Vaccinal Encephalitis, *New Eng. J. Med.*, 204, 10: 475 (Mar. 3), 1931.

Intradermal Typhoid Vaccination—Injections of four small doses of anti-typhoid vaccine intradermally are suggested on the ground that the technic is simple, the immunologic response is satisfactory, and local reaction is much reduced.

TUTT, L. Active Immunization Against Typhoid Fever, with Particular Reference to an Intradermal Method, *J. Lab. & Clin. Med.*, 16, 6: 552 (Mar.), 1931.

Cold Vaccine—Successful but limited experience in preventing colds is reported in the prophylactic use of a vaccine comprising the more prevalent varieties of streptococci.

WALKER, I. C. Apparent Specificity Among Streptococci and the Cause of Some Failures of Mixed Streptococcus Vaccines in the Treatment of Chest Colds and Asthma, *J. Lab. & Clin. Med.*, 16, 6: 539 (Mar.), 1931.

Mental Health—Written from other viewpoints than that of the public health

officer, this series of papers still has much of interest for the sanitarian.

WILBUR, R. L., *et al.* Mental Health as a National Problem, *J. A. M. A.*, 96, 13: 994 (Mar. 28), 1931.

Rural Health Service—There are two fundamental facts: rural areas need the same health service the city gets; many cannot pay for such services. Collective responsibility presumes state aid, which is the only escape from the dilemma. The story of Cattaraugus leads to this conclusion.

WINSLOW, C.-E. A. Carrying Health to the Country, *Survey Graphic*, 65, 11: 610 (Mar. 1), 1931.

Getting Group Action—Remarks anent the new leadership as a means of stimulating creative thinking in and by a group. Addressed to a visiting nurse service board meeting, this excellent paper can be read with profit by all sanitarians.

WINSLOW, C.-E. A. The New Leadership, *Pub. Health Nurse*, 23, 3: 108 (Mar.), 1931.

Cancer Research—Absorbing indeed is this excellently prepared and brief story of 30 years of experimental study of the cause and growth of malignant disease. A wealth of material for health workers who would become publicists.

WOGLOM, W. H. Experimental Cancer Research, *Am. J. Med. Sci.*, 181, 2: 157 (Feb.), 1931.

NEWS FROM THE FIELD

SUMMER SCHOOL COURSES IN PUBLIC HEALTH

While the following list does not show all universities and technical schools offering summer courses in public health, it represents those who have replied to a questionnaire sent out by the American Public Health Association.

University of California, Berkeley, Calif.

June 22–August 1
Administration of Schools of Nursing
Elementary Epidemiology
Elementary Public Health
Public Health Nurse in Relation to the Community
Responsibility of the Public Health Nurse for the Health of the Adult
Supervision in Schools of Nursing

Columbia University—DeLamar Institute of Public Health, College of Physician and Surgeons

June 15–July 1
School Health Supervision—Medical Inspection, Mental and Physical Education

Teachers College, New York, N. Y.

July 6–August 14
Administration of Health Work in Schools
Child Hygiene
Health Care of Infants
Health Education in Elementary Schools
Home and Community Hygiene
Methods of Teaching in Fresh Air Classes
Methods of Teaching Lip-Reading
Nutrition and Health
Personal Hygiene
Principles of Public Health Nursing
Public Health Administration
Research in Child Health
Safety Education
School Nursing
Sight Saving Classes
Supervision in Public Health Nursing
Supervision of Health Education
Survey of Public Health Nursing

Cornell University, Ithaca, N. Y.

July 6–August 14
Gymnastics and Dancing

Health Supervision of School Children
Hygiene of the School Child and Adolescent

Measurements of School Children
Physical Education

Duke University, Durham, N. C.

June 12–July 22
Materials and Methods in Health Education
Materials and Methods of Physical Education

University of Georgia, Athens, Ga.

June 22–August 22
Behavior Problems in Children
Child Care and Training
Child Development
Child Study and Parent Education
Development of the Young Child
Diagnosis and Treatment of Exceptional Children
Educational Biology
Educational and Mental Hygiene
Educational Hygiene
Educational Sociology
Health Education
Mental and Educational Measurements
Physiology and Health
Play Activities
P. T. A. and Parent Education
Principles of Health and Recreation
Mental Hygiene
The Age of Adolescence
The Age of Childhood

Harvard University, Cambridge, Mass.

July 6–August 15
Principles and Problems of Hygiene, and Teaching Methods
Physical Education, Theory and Practice

University of Hawaii, Honolulu, T. H.

June 29–August 7
Health Education and Popular Health Instruction

University of Illinois, Urbana, Ill.

June 22–August 15

Health Education and Corrective Gymnastics
 Organization and Supervision of Health Education in the Elementary Schools
 Physical Education
 School Hygiene

State University of Iowa, Iowa City, Ia.

June 8–July 7 (First Term)

July 20–August 20 (Second Term)

Administration of Physical Education and Athletics
 Advanced Hygiene
 Corrective and Remedial Gymnastics
 Health Education Program in Elementary Schools
 Hygiene
 Hygiene of Swimming Pools, Gymnasiums, Camps
 Institutional Nutrition
 Medical Supervision of Athletics
 Organization, Administration and Supervision of Public Play-Grounds
 Organization, Administration and Supervision of Public Recreation
 Organization, Administration and Supervision of Public School Physical Education
 Principles and Methods of Physical Education
 Principles of Physical Growth and Measurements
 Seminar in Public Health

Johns Hopkins University, Baltimore, Md.

June 22–July 31

Elements of Hygiene and Preventive Medicine
 School Hygiene

Massachusetts Institute of Technology, Cambridge, Mass.

July 6–August 14

Bacteriology
 Health Education Methods
 Methods of Teaching General Biology
 Public Health Laboratory Methods

University of Michigan, Ann Arbor, Mich.

June 29–August 7

Administration and Organization of Public Health Nursing
 Applied Nutrition
 Child Hygiene
 Epidemiology and Communicable Diseases
 General Hygiene and Public Health

Industrial Hygiene

Medical Social Case Work

Mental Hygiene

Methods and Materials in Health Teaching

Principles of Public Health Nursing

Public Health Law and Administration

School Health Problems

Vital Statistics

Michigan State College, East Lansing, Mich.

June 2–July 31

Bacteriology

Hygiene

Medical Biology

Pathology

Physiology

University of Missouri, Columbia, Mo.

June 8–July 31

Nursing

Physical Education

School Hygiene

University of New Mexico, Albuquerque, N. M.

June 8–August 1

Educational Hygiene

New York University, New York, N. Y.

July 6–August 14

Child Hygiene

Education in Health

Health and Growth of School Children

Methods of Teaching Health

Principles of Teaching Health

Northwestern University, Evanston, Ill.

June 22–August 15

Personal Hygiene

University of Pennsylvania, Philadelphia, Pa.

July 6–August 15

Hygiene

Physical Education

Pennsylvania School of Social and Health Work, Philadelphia, Pa.

June 15–July 24

Nutrition

Public Health Nursing

School Nursing

Social Hygiene

Social Problems

Tuberculosis and Its Control

Rutgers University, New Brunswick, N. J.

June 29–August 7

First Aid
Preventive Medicine
Public Health

Stanford University, Stanford University, Calif.

June 18–August 29
Health Department Administration
Physical Education and Hygiene
Public Health Nursing

Syracuse University, Syracuse, N. Y.

July 6–August 14
Home Nursing
Hygiene

University of Virginia, University, Va.

June 22–August 1 (First Term)
August 3–September 5 (Second Term)

Biochemistry
Hygiene and Sanitation
Physical Education
Sex Character Education

University of Washington, Seattle, Wash.

June 17–July 27 (First Term)
July 27–August 27 (Second Term)
Advanced Nutrition

Bacteriology
Health Education Movement
Personal and General Hygiene
Physical Education Administration
Physical Education Methods
Principles of Physical Education
Principles of Public Health Nursing
School Hygiene
Supervision of Physical Education

Western Reserve University, Cleveland, O.

June 22–July 31
Foods and Health
Hygiene of the Child
Personal Hygiene

University of West Virginia, Morgantown, W. Va.

June 15–July 24
Health Education

University of Wisconsin, Madison, Wis.

June 29–August 7
Bacteriology
First Aid to the Injured
Supervision and Organization of Health Education
Tests and Measurements in Physical Education

PENNSYLVANIA PUBLIC HEALTH ASSOCIATION

THE Pennsylvania Public Health Association will hold its annual meeting at the Penn Harris Hotel, Harrisburg, Pa., June 18–19, 1931. Surgeon General Hugh S. Cumming has kindly consented to address the association at the dinner meeting of June 18.

FIRST BROADCAST OF HEALTH FILMS BY TELEVISION

THREE of the animated cartoons used by the Division of Public Health Education of the State Department of Health were broadcast by television through the courtesy of the De Forest Radio Company television station W2XCD, Passaic, N. J. The first film was sent out on March 30 and the other two on April 6 and 13 respectively. The hour of broadcasting in each in-

stance was 10 P.M. The films were accompanied by appropriate music, which are synchronized with the pictures.

Sight is transmitted from station W2XCD on 2,035 kilocycles while sound is transmitted on 1,604 kilocycles. The range of the station extends beyond the Mississippi River and from the Gulf of Mexico into Canada.

This broadcast is the first known attempt in history to send health films by television.

ENDEMIC TYPHUS FEVER

A REPORT recently made public by the U. S. Public Health Service shows that there is strong evidence to indicate that fleas may be the means of transmission of endemic typhus fever from person to person or from a possible rodent reservoir to human beings. This discovery is of much importance

and may be of value in the prevention of the spread of this disease.

NATIONAL SAFETY CONGRESS

EACH year during the past 18 years there has been held, somewhere in the United States, what has been called a "National Safety Congress."

These gatherings, which have gradually grown in size until they are now among the largest and best organized congresses of the world, are visible proof of the growth and importance of what likewise has been called "The Safety Movement."

The Congress this year will be the Nineteenth Annual Safety Congress and Exposition, to be held in Pittsburgh from September 29 to October 3.

SWEDEN

NEW legislation prohibiting the employment of workers less than 18 years old in certain occupations went into effect in Sweden on January 1, 1931. According to the labor law of 1912, which is still in force, the King has the authority either to prohibit the employment of persons under 18 in certain occupations or to permit it under certain conditions.—*Sociala Meddelanden*, Stockholm, 11: 872, 1930.

ROCKY MOUNTAIN SPOTTED FEVER

A DISEASE of the Rocky Mountain spotted fever type has been identified as occurring in states in the eastern and southeastern sections of the United States. Heretofore it has been thought that it existed only in the western part of the United States, being most prevalent in the Rocky Mountain section.

NEW YORK STATE SEWAGE WORKS ASSOCIATION

THE Third Annual Meeting of the New York State Sewage Works Association was held in Albany, N. Y., March 5, 1931. At the business meet-

ing W. P. Gyatt, Syracuse, C. A. Howell, Buffalo, and E. B. Phelps, New York, were elected to the Executive Committee in place of H. B. Cleveland, M. Cohn and G. D. Holmes, whose terms of office expired. John F. Skinner, Rochester, was elected President, and E. B. Phelps, Vice-President. A. S. Bedell, State Department of Health, Albany, was reappointed Secretary-Treasurer.

The next meeting of the association will be held in Freeport, N. Y., June 5-6, 1931.

PASTEURIZED MILK AVAILABLE IN JERUSALEM

THE pasteurization plant of the Straus Health Center in Jerusalem maintained by Hadassah, the Women's Zionist Organization of America, is now in operation. This means that a supply of milk, pasteurized under the most modern scientific conditions, is available in Jerusalem.

HOSPITAL CARE FOR NEGRO CRIPPLED CHILDREN

A NEW Duke memorial building for Negro crippled children was recently dedicated at the North Carolina Orthopedic Hospital, Gastonia. Its erection was made possible by a bequest for the purpose in the will of Benjamin N. Duke.

NOTICE OF THE WORLD FEDERATION OF EDUCATION ASSOCIATIONS CONFERENCE

THE fifth conference of the World Federation of Education Associations will be held at Denver, Colo., July 27-August 1, 1931. This organization seeks to coöperate with all organizations working for the advancement of world unity.

The Health Section, one of the many devoted to specific interests, has functioned actively in the promotion of school health programs. The meetings held at San Francisco, Calif., in 1923; Edinburgh, Scotland, in 1925; Toronto,

Ont., in 1927, and Geneva, Switzerland, in 1929, have been attended by representatives from all parts of the world and the reports issued by this section have an important place in libraries of teacher training institutions and in education and health administration offices throughout the world.

The program for the Health Section meeting at Denver is now being arranged and representatives of Latin-American countries will be heartily welcomed either as speakers or participants. All phases of the school health program will be presented and a representative audience of public health officers, doctors, nurses, physical educators, health educators, classroom teachers, home economists and other authorities is expected.

For further information address the secretary of the Health Section, Sally Lucas Jean, 200 Fifth Avenue, New York, N. Y.

HERMANN M. BIGGS MEMORIAL LECTURE

THE Memorial lectureship which bears the name of Hermann M. Biggs was founded by his widow. At first it was given under the auspices of the New York Tuberculosis and Health Association and the Medical Society of the County of New York. In 1930 it came under the aegis of The New York Academy of Medicine, and the first lecture as an Academy event will be given May 7, 1931.

The first lecture was delivered in 1925, by Dr. William H. Park, on "A survey of some broad phases of tuberculosis."

The other Biggs Memorial Lectures have been delivered by Dr. S. Lyle Cummins, in 1926, on "Clinical differences in tuberculosis"; Dr. Allen K. Krause in 1927, on "Tuberculosis and public health"; in 1928, Dr. C.-E. A. Winslow, who chose as his title "The contribution of Hermann M. Biggs to public health." Dr. John H. Stokes was the lecturer in 1929, speaking on

"The syphilology of today and tomorrow."

There was no lecture in 1930 and the program for this year, under the auspices of the Academy, will have as the speaker, Dr. George H. Bigelow, Commissioner of Health of the Commonwealth of Massachusetts.

EVAPORATED MILK SENT TO DROUGHT AREA

AS stated editorially in the March issue of the *Journal*, one of the most urgent needs in the drought area has been an adequate supply of pure milk. Sanitarians will be interested and gratified to learn, therefore, that in April 10 carloads of evaporated whole milk, the equivalent of nearly 350,000 quarts, were shipped to centers in Kentucky, West Virginia, Tennessee, and Oklahoma for distribution through local chapters of the American Red Cross.

This milk was donated to the Red Cross by more than 13,000 employees of The Borden Company of New York and its affiliates, who voluntarily raised a fund to purchase this milk from their own company at cost price.

This company has also donated to the Frontier Nursing Service of Kentucky about 1,000 pounds of powdered skim milk for relief purposes. This product is the equivalent of about 5,000 quarts of reliquified skim milk.

PROGRESS IN DISEASE PREVENTION

ACCORDING to the U. S. Public Health Service, the most significant advances in public health achievement have been manifested among the lower age groups. The great sanitary reforms, such as the filtration of water supplies, have remarkably diminished diseases of certain kinds among all ages and classes of persons, but the actual saving of life has been most pronounced among children, and especially little children and infants. It is for this reason that the expectation of life at

birth—that is, the average length of time that all children born at a given time will live—has increased from about 48 to about 58 years in the past 20 years.

CHRONIC SICKNESS COSTS 100 MILLION A YEAR

AT least 2 per cent of the population in New York City is constantly ill, and at least 70,000 persons in New York are continuously ill from chronic disease. Dr. Williams estimated that these individuals could ordinarily earn \$45,000,000 a year, and that it cost at least \$50,000,000 a year to care for them, so that the actual loss to the community on account of chronic illness was very close to \$100,000,000 a year.

ENGLISH SUMMER COURSES IN PARIS

THE Faculty of Medicine of Paris (the Medical School of the University) announces a series of postgraduate courses to be given in Paris, under the auspices of the Association for the Development of Medical Relations, a commission sponsored by the French Government. The work will be presented in the English language. Clinics, lectures and demonstrations will be conducted in the great hospitals of Paris, on a wide variety of topics, by eminent French clinicians. A nominal fee will be charged for each course.

Details may be secured by addressing directly Professor E. Hartmann, President of the "A. D. R. M.," Faculty of Medicine of Paris, 12, Rue de l'Ecole de Medicine, Paris (6e); or, in the United States, Dr. Frank Smithies, 920 North Michigan Avenue, Chicago, Ill.

FORMATION OF NEW SECTION OF THE CANADIAN PUBLIC HEALTH ASSOCIATION

FOR a number of years the need has been felt for a definite section of the association to be devoted to Public Health Engineering. As a result of the

expressed desire of a large and very representative group of engineers, the association has approved of the formation of this new section.

For the first year the officers of the association are as follows: *Honorary Chairman*, W. J. Bell, M.B., Deputy Minister of Health, Ontario; *Chairman*, George H. Ferguson, Dept. of Pensions and National Health, Ottawa; *Vice-Chairman and Secretary*, Albert E. Berry, C.E., Ph.D., Parliament Bldgs., Toronto. The plans for the Section including details of membership and appointment of committees will be presented at the first meeting of the Section, which will be held at Regina in June in the course of the annual meeting of the association.

There is every reason to believe that the new Section will prove a source of real strength to the association in its work of advancing public health in Canada.

PENNSYLVANIA'S RURAL HEALTH BUSES

THE Pennsylvania Department of Health, for six successive years, has sent to the rural sections of the state, motor cars fully equipped for the health examination of infants and young children. During the summer of 1930 it sent 2 cars to certain counties in the eastern part of the state, each car having a staff of 2 physicians, 2 dental hygienists, and 2 nurses. The cars were driven by medical students specially trained to give vision tests to 5 and 6 year old children. Over 8,000 children were examined, and 3,426 were referred for treatment to the family physician. Between 6,000 and 7,000 children had their teeth cleaned, and over 4,000 were recommended for treatment to local dentists.

PREVENTION AND CONTROL OF VENEREAL DISEASES

DURING the fiscal year 1930, state health authorities reported to the

U. S. Public Health Service 213,309 cases of syphilis and 155,875 cases of gonorrhea. The total of venereal infections thus reported exceeded the number of cases recorded during the calendar year for any other single communicable disease, omniprevalent measles not excepted. Data obtained from prevalence studies which have been made up to the present time appear to show that the incidence of syphilis and gonorrhea in the United States probably is much higher than that indicated by the state reports.

Estimates worked out from the results of these surveys place the prob-

able number of new infections for which treatment is sought during the course of a year at more than 1,000,000.

PURCHASE OF HAMILTON LABORATORY BY THE GOVERNMENT

FEDERAL purchase of the tick fever laboratory at Hamilton, Mont., has been authorized by Congress. This carries an appropriation for enlarging the building. It is expected this laboratory will be considered the western branch of the National Health Institute. The passage of this bill was a direct result of the splendid teamwork of the various health agencies of the country.

PERSONALS

ROBERT ALSTON MARTIN, M.D., Fellow of the A. P. H. A., for 32 years Health Officer of the City of Petersburg, Va., died April 1, 1931.

DR. FRANCIS M. MCCALLUM, of Kansas City, Mo., was elected president of the Missouri State Board of Health, January 26; Dr. Horace W. Carle, of St. Joseph, was elected vice-president; and Dr. James Stewart, of Jefferson City, secretary, was re-elected.

DR. GEORGE K. PRATT, of New York City, a nationally known psychiatrist, has been appointed Medical Director of the Mental Hygiene Committee of the State Charities Aid Association. Dr. Pratt, who, for the past six years, has been the Assistant Medical Di-

rector of the National Committee for Mental Hygiene, will serve in this new position on a part-time basis, and will also actively continue his staff connection with the National Committee.

ANNA GARLIN SPENCER, educator, author, theologian, humanitarian, social worker, and advocate of world peace, died February 12, 1931, at her home in New York. Dr. Spencer was Vice-President of the American Social Hygiene Association.

WILLIAM A. HAMANN, after almost half a century in the chemical manufacturing industry, recently retired as chairman and director of the Roessler & Hasslacher Chemical Co., Inc., New York, N. Y.

View of Health and Disease Based on a Rise and Fall in the Levels of Life with Cycles in Vitamin Tides*

WESTON A. PRICE, D. D. S.

Cleveland, O.

VARIATIONS in susceptibility and resistance to disease have long been recognized as of paramount importance in determining individual health levels. The controlling factors for these variations have been but little understood, and prophylactic procedures have not been able to diminish materially the rate of apparent increase in diseases of the heart and circulatory system, and those of some other organs.

As an approach to the presentation of some new data I would suggest the viewpoint, at least for this consideration, that instead of individuals dying chiefly at this time from degenerative diseases we think of them as getting the degenerative diseases in many instances because they are in the process of dying.

This immediately raises the question as to why they are in the process of physical degeneration or death. It apparently is not simply a case of the running down of a physico-chemical mechanism since we have a series of cycles of degeneration, and when we compare the characteristics of the mortality and morbidity curves throughout a series of annual seasons we find that in various parts of the world there is remarkable constancy in the nature of the curves. This will be seen clearly in Figure I, which presents curves for mortality rates for pneumonia and heart disease for the United States, England and Wales, and New South Wales (Australia), for comparison. The similarity will immediately be seen to be most striking whether reading across the page or up and down. There is, in general, a rise in mortality in winter and a fall in summer. Our concern is why.

* Read at a Joint Session of the Food, Drugs and Nutrition and the Child Hygiene Sections of the American Public Health Association at the Fifty-ninth Annual Meeting at Fort Worth, Tex., October 27, 1930.

It is clear that we are dealing with a force or forces fundamental to life itself, having an expression which bears a distinct relationship to seasons. This rise and fall in the level of life has an almost endless variety of expressions. Since animal life can only exist by using as nutrition directly or indirectly organic compounds developed by plant life, and the plant can use only binary compounds which it builds into ternary and higher compounds, we will look for characteristics of the plant foods to find, if possible, factors that will be related directly and indirectly to the characteristics of the morbidity and mortality data.

In order to make the problem still more specific it seems important to study the characteristics of those products which are most efficient in maintaining both life and physical development. There are many different types of plant foods available for the sustenance of life, both on the land and in the sea, all of which go back directly or indirectly to the chlorophyll of plant life.

It is of particular significance that the great group of the animal kingdom constituting the mammalia are characterized by their dependence upon milk for a period of growth in early life. We have in this fluid the only single food capable of sustaining life and growth, and a product that is remarkably uniform, regardless of the species from which it is obtained. Since milk contains the essentials for life and is the product of plant life, it may and probably does contain expressions of variation in those controlling factors which are involved in the rise and fall in the levels of life, for it contains the elements which maintain life.

The products of the pasture must contain essentials for life, both mineral and accessory, and since so many varieties of plant life can provide the requirements for milk, we probably have in milk the best index for studying these requirements in fluids.

The last two decades, and particularly the last few years, have rapidly increased our knowledge of the accessory food factors—those obscure products which make the difference in the levels of life, for when they are decreased below a certain minimum life cannot exist. These activators or vitamins may be divided into two groups, the water soluble and the fat soluble; while both are essential and both are subject to fluctuations, our chief emphasis in this review will be centered on the group which is most difficult to obtain, namely, the fat soluble vitamins. Contrary to the general conception, the sources of some of the fat soluble vitamins and activators are actually very restricted. Being fat soluble, they are found only in the small amount of fat that is present in growing plants and in certain of the fats of animals, chiefly stored there from plant life.

COMPARISON OF VITAMINS A AND D IN BUTTER BY MONTHS FOR THREE YEARS, 1928, '29, AND '30.

FIGURE II—Average levels of vitamins A and D for a 5-state area

It now seems probable that the principal reason milk is the infant food of so large a group of the animal kingdom is because the parent is able to take these fat soluble factors from plant life, or from the tissues of animals in which they have been stored, and make them available in the suspended fat of the breast food. The variations in mineral content of milk produced under varying conditions are found to be very much less than those in both the water soluble and fat soluble activators, both of which are essential. We are, however, primarily concerned with the variations in the fat soluble vitamins. The fat soluble activators which are chiefly responsible for mineral utilization are found in large quantities in only two important sources of food, the fat of some milk and the oils of some fishes.

Since mineral utilization is essential for the building and maintenance of all tissues of the body, particularly the bones and teeth, we are led at once to place great importance on those activating substances without which the minerals, though present, are not available for the animal body.

I am carrying out an extensive investigation on the variations in the levels of these activating substances in the fats of milk. This involves a study of the level of the fat soluble activators in dairy products as obtained from many countries throughout the world. Samples are being received from countries in both Northern and Southern Hemispheres, regularly monthly, weekly or every 2 weeks. The Alaska products include reindeer milk, butter and cheese, beside marine-life oils. The number of butter and cream samples received during the summer season this year reached 700 per month. It is ex-

ceedingly significant that there is evidence of a seasonal cycle in practically all of the countries of the world so far studied.

In Figure II will be seen graphs for the average level by months for both vitamins A and D for a 5-state area for 1928, 1929, and 9 months of 1930. The vitamin A level is shown by the broken line and is the average for all samples for this area, and vitamin D is shown by the solid line. The outstanding feature is the low level of available fat soluble vitamins in the dairy products from November to May in many districts in the northern latitudes where the spring or summer rise comes much later than in the less northerly latitudes. Note that the vitamin levels for 1929 are shown to be higher than 1928 and higher for 1930 than for 1929.

In Figure III we see the relation of deaths from pneumonia in 4 cities to the level of a factor obtained by adding the vitamin units A and D. The curve for deaths from pneumonia is shown by the solid line and the vitamin A plus D curve by the broken line. It will be seen that there is a remarkable similarity in the pneumonia curves for these various cities, all having their high point in the late winter and the low point in the late summer; also, that in general these factors are in opposite phase to the vitamin level as expressed in the butter fats obtained throughout the months for this area.

The finding of such a relationship for one district may be coincidence. It is important to apply the principle to many districts. This I have accomplished by dividing the United States and Canada into 16

FIGURE III—RELATION OF DEATHS FROM PNEUMONIA IN FOUR CITIES TO LEVEL OF VITAMINS A PLUS D BY MONTHS

OHIO, INDIANA, ILLINOIS, MICHIGAN, AND WISCONSIN

RELATION OF DEATHS FROM PNEUMONIA AND HEART DISEASE TO LEVEL OF VITAMINS A+D BY MONTHS, UNITED STATES OF AMERICA AND CANADA BY GEOGRAPHIC DISTRICTS.

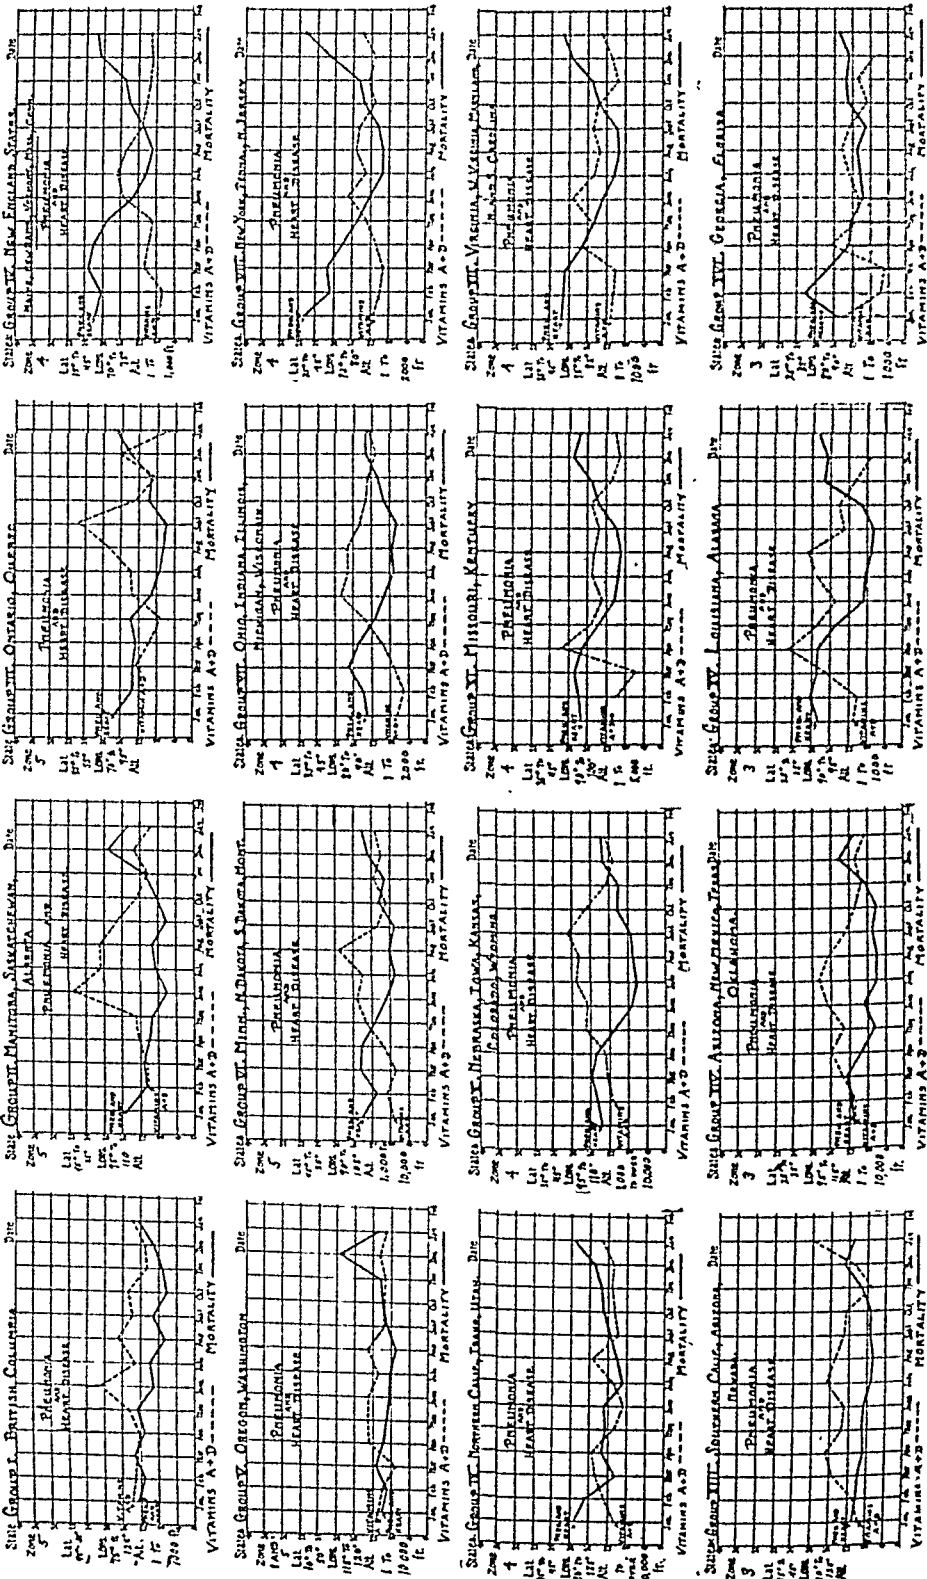

FIGURE IV

large geographic areas in the general order of their physical location as shown in Figure IV.

The solid line is a composite curve showing the deaths from pneumonia and heart disease and the broken line shows vitamin A plus D as expressed in the data obtained from the analyses of the butter and cream samples received month by month in 1929 from many places. In general when the vitamin curve is low the mortality curve is high.

There are two great sources of fat soluble food activators, namely the pastures of the sea and those of the land. Many people have the opinion that fish oil, particularly cod liver oil, would be a complete substitute for the fat soluble vitamins of land plant origin. In my clinical and technical investigations of the activators for inducing mineral metabolism, I have continually found evidence indicating that cod liver oil contains products that are very seriously toxic to humans and other land animals and can do much harm when given in large doses, even only as large as frequently advocated.

If it be true that we are dealing in these matters with factors that are related as cause and effect, it should be true also that data would readily be obtainable, throwing light on this whole problem by changing the incidence of morbidity and mortality as a result of administering or utilizing butter fat vitamins during periods of such low vitamin tides. Since dental caries is said to be the most universal disease in the world and is so important because of its significance as a nutritional disturbance, its prevention becomes one of the prime needs in any program for health betterment.

A study was made of 200 individuals during the fall, winter and spring of 1929-1930, on the basis of the development of dental caries (Figure V). Diagnosis included the use of X-rays at different periods and detailed instrumental examination. One group received no additional activators to those available in their regular dietary. Those in this group are shown for the different age periods by the dotted line; the solid line shows the number of cavities per individual in the various age groups for those receiving additional activators provided them each week in capsule form. It will be seen that there is a very marked difference in extent of dental caries of the two groups, amounting to tenfold as many cavities in those not receiving the additional activators as in those receiving them. In addition to the activators there was considerable counsel given regarding the selection of the dietary in general.

In 20 individuals between the ages of 10 and 20 not receiving additional activators, there was a total of 143 cavities when examined in the late spring and early summer of 1930, whereas in the group re-

EFFECT OF VITAMIN CAPSULES ON DENTAL CARIES BY 10 YEAR AGE GROUPS.

FIGURE V—Progress in control of dental caries, by difference in number of cavities developed per individual in group receiving special activators and those not receiving them.

ceiving additional vitamins there were only 3 cavities found in the 20 individuals. The additional activators were given in capsule form, each capsule containing 0.6 gm. Usually two capsules were taken with each meal. The capsules contained a mixture of the activators as concentrated from an exceptionally high vitamin butter, with about an equal quantity of an exceptionally high vitamin cod liver oil, both of which were selected by means of chemical tests. The improvement in general health, freedom from colds and capacity for work was very marked in all of these age groups receiving the capsules.

Since it is true that normal growth and maintenance of health are dependent upon the availability of the building blocks for growth, function and repair, it is not sufficient that we provide only the energy factors and the minerals, but also the activators with which these factors may be utilized. These apparently must come chiefly from plant sources. If the plant does not find in the soil the essential factors, chiefly mineral, and radiant energy out of which it can build its structures including its activators, it cannot provide for animal life those other building blocks without which animal tissues cannot be built or maintained.

When we study a map showing the locations where heart disease is most severe and on the increase, we find we are dealing in general with those areas that have been longest populated and the soil partly

depleted of such minerals as phosphorus, calcium, magnesium, potassium, etc. This newer view of disease, or the lack of growth and the maintenance of function, seems related primarily to the absence of this newer group of forces, the activators, and we see more clearly why we have the annual pilgrimages to the hospitals, and that many conditions we have thought of as diseases are really symptoms.

SUMMARY

Very little emphasis seems to have been placed upon or importance attached to the fact that annual tides have existed producing rhythmic rise and fall in the levels of vital phenomena. I have placed much emphasis upon the fact that the very existence of the tides as rise and fall in the levels of life is itself the indisputable evidence that the phenomena are related directly to factors which are variable from month to month in cycles.

Since the newer knowledge of the rôle of the activators, including vitamins, has shown them to be fundamental contributing and even controlling factors in growth and function; since all animal life is dependent upon plant life for its food supply; since the fat soluble activators are in general the most difficult to obtain; and since milk is the only single food that makes available all the various factors essential for life and growth; it has been used as the chief food product for these studies.

Intensive studies over a period of several years have revealed variations in the level of the fat soluble activators of milk which are traceable directly to the food of the animals providing the milk. The winter rise in morbidity and summer fall in the same seem to have some relation to the sun's position and to the growth of plants through the activity of the chlorophyll, which produces activating substances which are essential for animal life.

The extension of this study to dairy products obtained from many countries distributed throughout the world in both hemispheres demonstrates the presence of this relationship. The application of the principles involved by the administration of the fat soluble activating products that are obtainable from actively growing plant foods, particularly from milk fat produced from such foods, is found to be capable of effecting a very marked amelioration of the pathological phenomena associated with a reduction of infection through increased resistance as a defensive reaction, and in general is preventing the recurring cycle of morbidity in many individuals.

The accumulating evidence suggests the consideration of disease being, in many cases, more correctly speaking, a symptom and that

individuals often, instead of dying because they contract disease, primarily develop disease because they are dying. This interpretation provides an explanation for the increasing incidence of several diseases in particular localities, and seems to be associated with a depletion in the activating products of plant foods in these districts in part or chiefly the result of soil depletion of essential chemicals for efficient plant development, since these chemical elements are essential to the plant for creating these vitalizing activators which are essential for animal life.

To the extent to which these interpretations are correct, there is need for a change of emphasis in health programs from prophylaxis which has been found to be only partially effective, to an increase in the required activators partly by an improvement of soil conditions in order that plant life may be improved in quality, both for its use as food for humans and for the improvement of the nutrition of the foster mothers—the dairy animals—around which our civilizations have been built. This I interpret to be the means in the light of the best available knowledge for meeting the challenge of not only the Nordic races in the temperate zones, but for the betterment of human life wherever found; namely, to make available not only the mineral and other chemical elements needed for body building and repair, but also the vitalizing factors or activators, some of which are the known vitamins.

Physical Findings in New York City Continuation School Boys*

An Element in the Vital Statistics of Adolescents

JEROME MEYERS, M. D.

Supervising Physician, New York City Department of Health, New York, N. Y.

THIS is a preliminary and general medical and statistical study of material derived from personal examination of 2,691 working boys, 14 to 17 years of age, examined during 3 years—1926 to 1929—at the West Side Continuation School in the borough of Manhattan, and from selected items from examination of 4,661 boys in the Brooklyn Boys' Continuation School during the year 1929–1930 by the writer and three other physicians under his supervision.

The first group was part of the examinations of boys and girls done in a 3-year experiment in which three agencies coöperated: the New York City Department of Health through the Division of Industrial Hygiene, Dr. E. S. Morton, chief; the New York City Department of Education through the Director of Continuation Schools, Mr. Siegel, and Charles Degen who was in active educational charge; and the Public Educational Association through Mrs. Kinney, together with the Academy of Medicine through Dr. Corwin and with a number of advisory medical committees. The Brooklyn work is being done under the same agencies of the Health and Education Departments and the Kings County Medical Society, the participation of which medical organization is a novel and highly important excursion in public health work.

In this paper it is desired to give not only the results of the examination, but to discuss the possibilities of standards of history taking, of methods of physical examination, and of diagnosis; to point out the medical peculiarities of this group; and to add to our general knowledge of the diseases and vital statistics of these 14 to 17 year old boys as far as it has been possible to analyze and correlate the findings at present. No extensive or full data exist in medical books or literature on this group; as the work has progressed, more than one

* Read before the Vital Statistics Section of the American Public Health Association at the Fifty-ninth Annual Meeting at Fort Worth, Tex., October 27, 1930.

condition of interest has appeared and has led to the belief that a certain medical hiatus might begin to be filled. Infancy and childhood have been widely and exhaustively combed and studied, but the adolescent age of 14 to 17 is more or less of a medical *terra incognita*.

The boys were either workers or prospective workers. A thorough history taken by a nurse is followed by a thorough physical examination by the doctor. The history (Table I*) covers family, home conditions, recreations, habits, subjective symptoms, previous diseases, vaccination, industrial diseases, diphtheria immunization, accidents, and operations. The physical examination (Table II*) covers all the systems and special organs and aims to yield as careful and expert a search for physical defects as can be given in any private physician's office. It will be understood that X-ray and laboratory tests are not done but are recommended in every case where they are considered necessary for diagnosis or treatment.

The doctor lists the defects on the chart, also making a list for the pupil to take home for the parents or doctor and for the teacher's records. To the pupil is explained the results of his examination, the meaning of each defect for the present and its import for the future, and directions are given for remedying the same by simple hygienic measures, by reference to his private physician or, if a physician cannot be paid, to a clinic. This medical advice is supplemented by classroom instruction in a series of lessons developed by Mr. Degen on personal and applied hygiene based on the defects revealed by medical findings. All efforts are made to obtain the written opinion of the private physician and to record all reports from clinics.

The boy is called the following week when he is again examined and questioned as to what he has done, and is called weekly until normal. Records of these follow-ups are placed on the chart in code showing weight, improvement, cure, etc., and full notes are kept as to visits to physicians or clinic. If no coöperation is attained in the serious cases, a home visit is made either by the teacher or social worker. At the end of 6 months a reëxamination entailing another complete history and physical examination is made for each boy whether originally normal or not.

In addition to the above method used in Manhattan, very important pioneer aid has been rendered in Brooklyn by the Kings County Medical Society through its secretary, Dr. Alec Thomson. To this organization is sent by the examining doctor the name and address of the boy, also of his private physician together with a list of defects found in any case that is considered serious. The medical society then com-

* Available upon request to Dr. Meyers.

municates such information in writing to the physician, asking him to communicate with the boy and arrange for medical supervision of the case. I believe the many sincere responses received from private physicians have demonstrated the great benefits to the boys and the helpful and hopeful basis for coöperation between private and public medicine.

A tabulation of the physical defects found in the original examinations of 2,691 boys (Table III*) was compiled by the statistical department of the Metropolitan Life Insurance Co.† There were 6,522 defects or 2.4 per boy compared with 1,423 in 728 boys examined by me in Brooklyn, or 2 per boy. Twenty-three hundred and thirty-six, or 86.5 per cent, showed one or more defects. There were 13.2 per cent normal, compared with 12.8 per cent in 728 and 10.5 per cent in 2,940 examined by four physicians in Brooklyn.

The most common defects in order of frequency were:

Unclean teeth	Flat-feet	Round shoulders
Underweight	Delayed adolescence	Habitus asthenicus
Dental caries	Palpable tonsillar glands without tonsillectomy	Adenoids
Cervical adenitis	Chronic pharyngitis	Chronic otitis media
Uncorrected visual defects	Suspected old tuberculosis	Defective hearing
Pyorrhea	Acne	Rickets
Excessive cigarettes	Impacted wax	Chronic heart disease
Flat chest	Coated tongue	Constipation
Visual defects corrected but glasses not worn	Anemia	Scoliosis
Poor muscular development	Lack of bathing	Diseased tonsils
Nasal obstruction	Bad breath	Enlarged liver

Considering unclean teeth a defect, they showed the largest number, 1,593 or in 59.2 per cent of the boys. Normal except for unclean teeth were 332, or 12.8 per cent in 728, and 10.8 per cent in 2,940 boys examined by four physicians. If we do not consider unclean teeth a bar to a normal physical condition, we can list 25.5 per cent normal in Manhattan against 25.6 per cent in 728 boys, and 21.4 per cent of 2,940 reported by four physicians in Brooklyn.

Underweight, based on more than 10 per cent under the averages of the Baldwin-Wood Scale, gave 527 or 19.6 per cent, compared with 8.4 per cent in 728 boys, and 8.2 per cent in 2,063, by two doctors in Brooklyn. Overweight, based on more than 10 per cent above averages, showed 48 or 1.8 per cent, compared with 9.5 per cent in 728; 14 other cases or 0.5 per cent were listed as obesity compared with 15 or 2 per cent in 728. Malnutrition gave 85 or 3.2 per cent compared with 1 or 0.1 per cent in 728.

Organic heart disease listed 31 or 1.2 per cent, against 3.3 per cent

* Available upon request to Dr. Meyers.

† Thanks are hereby expressed to Dr. Dublin, Statistician of the company, in giving the facilities of his department for the tabulation and to Edwin W. Kopf, Assistant Statistician in active charge, for his constant friendly encouragement and valuable suggestions.

in 728, 1.5 per cent in 1,335, 2.7 per cent in 440, and 3.2 per cent in 437, or 2.5 per cent in 2,940 in Brooklyn. Cardiac anomalies (various murmurs in conditions not regarded as indicative of organic heart disease), 11 or 0.4 per cent, against 2.2 per cent of four physicians.

In 89 or 3.3 per cent, there was cause for suspicion of old healed tuberculosis of the lungs, while in 728 cases 9 or 1.1 per cent were found. *Habitus asthenicus* was present in 38 or 1.5 per cent against 0.7 per cent in 728. Two cases of active tuberculosis were listed against none in 3,410 boys among three doctors in Brooklyn. In 19 or 0.7 per cent, a family history of tuberculosis was elicited. In three cases a cervical adenitis was considered tuberculous in origin. In 14 or 0.5 per cent old plastic pleurisy existed; in 7 cases chronic bronchitis, and in 2 asthma. *Pyorrhea* gave 171 or 6.4 per cent against 3.5 per cent in 728. Enlarged tonsils were 121 or 4.5 per cent, compared with 1.8 per cent in 728 and 4.8 per cent in 4,661 by four doctors; diseased tonsils 23 or 0.9 per cent against 2.1 per cent of 728 and 2.6 per cent of 4,661 boys by four doctors.

There were 259 or 9.2 per cent with distinctly palpable, large cervical glands against 3.6 per cent in 728, and 100 or 3.7 per cent of hard or enlarged tonsillar glands or nodes without tonsillectomy, against 4.5 per cent in 728. Only two such cases were found after tonsillectomy against 4 in 728.

Anemia gave 61 or 2.3 per cent compared with 17 or 2.5 per cent in 728. Constipation showed 26 or 0.9 per cent against 21 or 2.9 per cent in 728 and 68 or 2.4 per cent of 2,940 boys among four physicians.

There were 23 or 0.9 per cent of enlarged liver, of which 3 were associated with catarrhal jaundice, 6 with coated tongue, and 14 with constipation. This compares with 20 or 2.7 per cent in 728 cases, of which 11 were associated with constipation, 8 with coated tongue and 1 primary. There were 90 boys or 3.4 per cent with coated tongues, of which 6 showed enlarged liver, only 1 constipation, 1 chronic gastritis, and 3 bad breath.

There were 75 cases of acne or 2.8 per cent, 3 of psoriasis, 13, scabies; 21, warts; 29, chronic eczema; 3, *tinea versicolor*; 9, herpes; 1, *pityriasis rosea*; 6, *trichophytosis*; and 3, *ichthyosis*. There were 41 or 1.5 per cent of round shoulders, 12 or 0.4 per cent of moderate kyphosis, none of which was apparently of tuberculous origin, 27 or 1 per cent of scoliosis, 145 or 5.4 per cent of poorly developed musculature, and 158 or 5.9 per cent of flat or undeveloped chest. Poor musculature and flat chest might exist in the same boy as many exhibited 2, 3, 4, and even 7, 8 or more defects. Flat feet showed in 106 or 3.9 per cent.

Excessive cigarette smoking was found in 165 or 6.1 per cent, and in Brooklyn in 3,410 boys by three doctors in 9.7 per cent. The total number of smokers among the 3,410 boys was 1,049 or 30.9 per cent, and of these 32 per cent or nearly one-third were considered excessive users. As to eyes, 196 or 7.3 per cent had uncorrected defective vision, 130 or 5 per cent corrected vision, 146 or 5.4 per cent had obtained glasses but were not using them. As to ears, there were 7 cases of acute otitis media, 35 or 1.2 per cent of the chronic form, 3 of acute mastoiditis, 78 or 29 per cent of impacted wax, and 34 or 1.2 per cent of defective hearing. There were 39 or 1.3 per cent of probable adenoids.

Listed are 13 or 0.5 per cent of inguinal hernia, 11 of undescended testicles, 7 of varicocele, 5 of hydrocele of the cord, 2 of acute gonorrhea, 2 of hermaphroditism. In the nervous and endocrine systems, 11 cases of very "nervous" or neurasthenic type, 21 with residual evidence of old paralysis due to poliomyelitis, birth-palsies, or encephalitis lethargica, 4 of hyperthyroidism, 9 of gonadal dysfunction, 5 of pituitary, 103 or 3.8 per cent with delayed adolescence (small genitalia, little or no pubic hair), against 1.1 per cent in 728 in Brooklyn, 5 of simple goiter, and 13 of feminism.

The following items are of interest:

Canities	4	Epilepsy	2
Exophthalmos	1	Chorea	2
Blindness in 1 eye	5	Hydrocephalus	1
Cauliflower ear	1	Microcephalus	1
Frontal sinusitis	1	Excessive exercise	2
Maxillary sinusitis	1	Lack of exercise	16 (0.6%)
Hutchinson's teeth	8 (0.3%)	Fatigue	1
Rickets	31 (1.2%)	Bad breath	48 (1.8%)
Lobar pneumonia	1	Insufficient sleep	5
Unresolved pneumonia	1	Hereditary lues	4
Emphysema	1	Wassermann test advised	25 (1%)
Congelation, dry-ice	1	Urinalysis advised	24 (1%)
Enteroptosis	5	Diabetes mellitus	1
Gastroptosis	2	Excessive tea or coffee	9 (0.3%)
Chronic appendicitis	3	Stuttering or stammering	23 (0.9%)
Acute appendicitis	1	Possible benzol poisoning	2
Rectal abscess	1	Lack of animal protein in diet	3
Pyloric obstruction	1	Lack of vegetables	1
Traumatic cholecystitis	1	Hemophilia	1
Basal metabolism test advised	3	Dirt-eater	1

As stated, each boy underwent a second complete examination at the end of 6 months. Table IV,* prepared by the statistical department of the Metropolitan Life Insurance Company, shows the results in 485 of 2,691 boys so examined as to total and individual defects remedied or improved. Of 1,223 defects found at first, 583 or 47.7

* Available upon request to Dr. Meyers.

per cent were cured, or bettered. On first examination there were 2.5 defects per boy; on the second 1.2. It will be understood that in the interval the boys were seen weekly many times for follow-up examinations and medical advice and that many had been to physicians or clinics or followed hygienic advice.

For underweight, 35 or 31.5 per cent of the original 111 became normal; these had been advised as to diet and exercise or had consulted physicians for tonics, but it must be remembered that some of these boys may in the natural course of development gain requisite weight. In malnutrition, 8 or 32 per cent of 25 became normal; defective vision, 19 or 52.8 per cent of 36; defective tonsils, 16 or 57.1 per cent of 28; carious teeth, 27 or 61.4 per cent of 44; unclean teeth, 104 or 35.1 per cent of 296; pyorrhea, 20 or 58.8 per cent of 34; organic heart disease, 2 or 22.2 per cent of 9; acne, 7 or 58.3 per cent of 12; cervical adenitis, 19 or 48.7 per cent of 39; anemia, 8 or 47.1 per cent of 17; poor personal hygiene, 7 or 77.8 per cent of 9; excessive cigarettes, 8 or 44.4 per cent of 18; and 236 or 61.9 per cent of 381 other miscellaneous defects. These are excellent results and corroborate the impression of real interest in most of the boys in their condition, their coöperation with the examining doctor, the aid of the private physician, the sincere effort of the examining physicians, and the general excellence of the interrelated activities of the educational, social and medical agencies in the experiment.

In the original 2,691 examinations there were found 6,522 defects divided into 234 separate medical or surgical conditions. From the clinical aspects all these findings are of importance for present health and prevention of future diseases; but the group does not evidence many acute threatening conditions. This adolescent group, just as it shows a marked tendency to growth, displays a distinct resistance to disease. Analysis of the findings in this light and a consideration of other and comparative statistics will be of interest.

For 1919-1920 the death-rates¹ per 1,000 white males living at ages considered, U. S. Registration Area, were: under 1 year, 84.33; at 1, 17.59; at 2, 8.45; at 7, 3.01; at 12, 2.20; at 17, 3.93; at 22, 4.94; at 27, 5.97; at 32, 6.89. For New York City as a whole they were: under 1 year, 89.45; at 1, 23.07; at 2, 9.46; at 7, 3.65; at 12, 2.24; at 17, 3.83; at 22, 5.49; at 27, 6.21; at 32, 7.41. From under 1 year then there is a fall to 12; at 17 the rate has begun to rise and continues to rise until at 77 years with 111.20 per 1,000 it is far above infancy rates. In 1920, 8.6 per cent of the total male population of the United States was in the group 15-19. For the intercensal periods from 1880 to 1920 this group has increased 31.2, 15.4, 20.7, and 3.2 per cent.

Table V* prepared for me by the Bureau of Records of the Health Department, shows the causes of death in the Borough of Manhattan for 1929, ages 14, 15, 16 inclusive for males and females. Deaths numbered 62 at 14 years, 67 at 15, and 81 at 16. Among the causes were typhoid, 1; scarlet fever, 1; diphtheria, 2; influenza, 4; epidemic cerebrospinal meningitis, 10; tuberculosis, 45, of which 35 were of the respiratory system; cancer, 5, of which the stomach, lung and pancreas were each 1 and the bones 2; benign tumors, 6; acute and chronic articular rheumatism, 10; anemia, 1; leukemia, 1; ear and mastoid, 9; heart disease, 19, of which 16 were of chronic endocarditis; appendicitis, 6; hereditary syphilis, 1; chronic nephritis, 4; bronchopneumonia, 3; lobar pneumonia, 12; suicide, 1; homicide, 6; accidents, 32. In the 4 cases of influenza, 3 gave pneumonia and 1 heart disease as contributory to death.

The principal causes of death are then tuberculosis, accidents and heart disease with lobar pneumonia, rheumatism, epidemic cerebrospinal meningitis, mastoiditis and appendicitis following. For the boys, accidents head the list with 23, then tuberculosis, 18; lobar pneumonia, 8; heart disease, 6; epidemic cerebrospinal meningitis, 6; cancer, 5. The male and female population at these ages for 1920 in Manhattan are about equal. The deaths show for respiratory tuberculosis, 23 females to 12 males; chronic endocarditis, 10 females to 6 males; lobar pneumonia, 8 males to 4 females; accidents, 23 males to 9 females; cancer, 5 males to no females. The mortality rate in our age group is then low, and the morbidity causes outside of tuberculosis and heart disease, which are known to be low, not alarming.

GROWTH AND DISEASES IN AGE GROUPS

Minot,² in his classical work on age, growth and death, gives the yearly percentage increments in weights for boys from the end of 9 to the end of 10 as 11.6 per cent; 10-11, 6.5 per cent; 11-12, 7.1 per cent; 12-13, 7.9 per cent; 13-14, 11 per cent; 14-15, 11.7 per cent; 15-16, 15.7 per cent; 16-17, 10 per cent; 17-18, 4.9 per cent; 18-19, 1.9 per cent. Just in our age group the body has a recrudescence of growth. In girls this development occurs 2 years earlier. Sydenstricker,³ in his Hagerstown morbidity studies, notes that each period of life is characterized by its own distribution of illnesses, that in childhood respiratory, communicable, skin, ear, eye, tooth, nervous and digestive conditions and diseases cause most illnesses; that in old age heart, kidney and nervous conditions cause most illnesses; but in adolescence and

* Available upon request to Dr. Meyers.

young adult ages illnesses from all these causes are at their lowest levels. As the work on our age group of boys has progressed, impressions as to incidence of disease in general and the occurrence or lack of occurrence of certain conditions have become stronger. It will be interesting to analyze our findings and to compare them with existing statistics.

Gonorrhea—In the Manhattan study of 2,691 boys only 2 cases, or 0.3 per cent, of gonorrhea were found, both acute. In the Brooklyn group, among 728, no cases, and in 4,661 of four physicians, 5 cases or 0.1 per cent. It is possible that some chronic cases escaped detection, but as the boys were stripped for this examination, it is unlikely that many acute cases were missed. This lack of gonorrhea is rather striking. Brunet and Edwards,⁴ in a survey of Detroit physicians, hospitals, and clinics, for May 15, 1926, report 8,070 cases of gonorrhea under observation. Of these, boys under 16 showed 1.1 per cent for acute cases and 0.9 per cent for chronic. Females under 16 showed much greater numbers. Deacon,⁵ in his Michigan study of 29,741 cases of gonorrhea, reports a low incidence to about 15 when a rapid rise to a top in the group 20–24 occurs. This holds also for gonorrhea and syphilis combined. Among girls, the rates are continuously higher until 22. Out of 21,677 gonorrheas in white males, 49 were 10–14, 2,264, 15–19, and 8,190, 20–24. Somewhere between 10–14 and 15–19 there is a marked increase from 0.2 per cent to 10 per cent, but we found no such high incidence in our 14–17 groups, but figures comparable to Deacon's 10–14 group.

Syphilis—No case of the acquired form was found in Manhattan. In Brooklyn, 2 cases were so diagnosed in 4,661 by four doctors; the 2 by one doctor in 1,347 boys. In Manhattan 8 cases of Hutchinson's teeth occurred and in 25, or 1 per cent, a Wassermann was advised on suspicion of hereditary lues. In 728 boys in Brooklyn, 3 were listed as hereditary lues and 6 or 0.9 per cent were advised to have a Wassermann. In the Deacon⁵ study of 15,486 male syphilitics, 117 were 10–14; 496, 15–19; 2,548, 20–24. How many in the earlier ages are hereditary is not stated. Brunet and Edwards⁴ in the Detroit study for the male acute syphilis cases (infection 1 year or less) report 6.2 per cent occurring under 16 years. We may have failed to discover all cases, but out of 7,352 boys in the 2 schools there were found only 7 cases or 0.09 per cent of gonorrhea and 2 or 0.03 per cent of acquired syphilis. We are then dealing with a group showing little venereal infection, a finding of importance in statistical and diagnostic knowledge for the examiner and of possible preventive and social value to the boy.

Abdominal Conditions—Only 26 or 0.9 per cent of constipation were found. As in early infancy and childhood and in adult life constipation is regarded by physicians and laity as quite common, this adolescent group would seem quite free. In Brooklyn, 21 or 2.9 per cent of 728 and 68 or 2.4 per cent of 2,940 among four doctors were found. Most of the cases were not severe or persistent; an occasional constipation for 2 or 3 days. In Brooklyn, special attention was directed to the number of daily bowel movements; most reported 1, or 1 and 2, and many, 1, 2 and 3 daily. Sydenstricker^a found no cases of constipation in his 5-9, 10-14, 15-24 age groups, and gives annual rates per 1,000 for all ages of 8.5 per cent, for ages 0-4, 11.3 per cent; 25-44, 12.9 per cent; 45-64, 11.6 per cent; 65 and over, 37 per cent. These findings as with his others are not strictly comparable to those findings of our group as he would find such conditions only when reported as a major cause of illness, as he says, while our survey is based on intensive general history taking and examination. Our adolescent group shows a healthy and active intestinal system and should offer a field for dietary and physical instruction in the avoidance of future constipation. In 14 of the 26 cases an enlarged liver was found; possibly these 14 represent the more persistent and severe cases.

In Brooklyn, 11 of 21 gave enlarged liver. Of 90 boys or 3.3 per cent with distinctly coated tongues, only 1 was associated with constipation, 6 with enlarged livers, 3 with bad breath and 1 with gastritis. In Brooklyn, 31 or 4.3 per cent of 728 showed coated tongues; of these 11 or 35.5 per cent were associated with enlarged liver, 1 with gastritis and none with constipation. It would seem in this group that coated tongues are not particularly associated with constipation, bad breath or gastritis, but more with enlarged liver. Bad or unpleasant breath in 48, or 1.8 per cent, was also not frequent in constipation. Negro boys often showed a markedly furred tongue for no apparent reason and Italians frequently had bad breath, due possibly to peculiarities in diet.

Attention is called to the infrequency of acute appendicitis, 1 case, and of chronic appendicitis, 3 cases. There may be a causal or pendant relation of appendicitis to the infrequency of constipation. Very recently the Metropolitan Life Insurance Company⁷ has reported its industrial insurance experience for deaths from appendicitis since 1911. For white males all age groups have shown a distinct increase except 10-14 with a decrease of 2.6 per cent, and 15-19 with a decrease of 2.8 per cent, against an increase of 20 per cent for all ages. For white females, only the 10-14, 15-19 and 20-24 groups show decreases. We again note distinct peculiarities in our adolescent group.

We note also that the group shows little or no diarrheal or irritative gastric or intestinal conditions. There seemed in the 2,691 boys and in the 728 in Brooklyn a very general knowledge and practice of a mixed balanced diet. Only 1 boy in Manhattan reported that he ate no vegetables; 3 reported abstinence from animal protein; only 1 was a faddist on raw vegetables. To what extent diet may be related in our group to the low incidence of constipation, appendicitis and other intestinal and gastric conditions or the active working life and the general vitality and resistance of these years is an interesting question.

Tuberculosis—Only 2 active cases were found and none in 2,490 among three doctors in Brooklyn. In Manhattan 89 or 3.3 per cent were listed as possible old healed pulmonary cases. The finding was based on dullness over one or both apices or other areas, abnormal breathing, limited apical projection fields or difference in width of the apices, or lack of expansion of the inferior limits associated with dull or limited apex. No attempt was made to differentiate between childhood and adult types of infection. Findings of 38 or 1.5 per cent of habitus asthenicus or phthisicus were listed, 19 or 0.7 per cent with ascertainable family history, 3 with a cervical adenitis with a childhood history of neck gland operation, 14 or 0.5 per cent of chronic plastic pleurisy, 7 or 0.3 per cent of chronic bronchitis, 2 of asthma, 1 of rectal abscess and 1 of tuberculosis of the eye. In this category our group is again comparatively free. Drolet⁶ gives the general tuberculosis rate per 100,000 for New York City for males living in each age group for 1928 as: 0-4 years, 53; 5-9, 12; 10-14, 13; 15-19, 66; 20-24, 110; 25-29, 114; 40-44, 180; and 60-64, 256. Chadwick⁷ in Massachusetts in the last two years found among 51,000 school children below high school age that 1.5 per cent showed the childhood type and 3.4 per cent were suspicious. Only 1 in 3,200 examined was of adult type. Based on Chadwick's findings, Bolduan⁸ estimates for New York City that nearly 20,000 school children should show the childhood type. In females, Drolet gives the peak for 1928 in the group 20-25 instead of being as formerly in 30-35 and concludes:

In a given 1,000 tuberculous deaths in New York City at the present time the age concentration among females is at 20-25 years; among males, 40-45; among negro males at 25-30, and white males 40-45; among both negro and white females at 20-25; among Jewish males, after 45.

Heart—Twenty-nine or 1.1 per cent were listed as organic heart disease. In addition, there were 2 diagnosed as athletic heart; they showed cardiac enlargement with a systolic apical murmur and a his-

tory of strenuous athletics. In 3 others, simple cardiac enlargement was noted; urinalysis was advised. In 13 or 0.5 per cent there was circulatory asthenia, in 24 or 0.9 per cent functional arrhythmia associated in 1 case with organic heart disease; in 46 or 1.7 per cent a tachycardia with pulse of 96 or more, most of which cases gave the impression of excitement due to the examination; in 2 a marked bradycardia of 42 and 48. A pulse of 60 in the boys was not infrequent. In 11 or 0.4 per cent there were murmurs, apical, basal aortic or pulmonic or combinations, with no enlargement, that were classed as cardiac anomalies, including open ductus arteriosus, patent foramen ovale, ill-defined pulmonic valve or artery conditions, but not respiratory murmurs. It was felt that such a grouping should be made as in these cases they should be told the murmur does not mean organic heart disease as might be erroneously diagnosed with a resultant impairment of his physical and industrial activity, and his peace of mind.

In the group of organic disease, many knew of no cardiac condition, none was seriously incapacitated, a few had moderate dyspnea on exertion, but all would be placed in Class I of the American Heart Association classification.

In Brooklyn of 728 boys I found 3.3 per cent of organic heart disease, one physician 1.5 per cent in 1,335; one, 2 per cent in 440; and one, 3.2 per cent in 437—an average of 2.5 per cent in 2,940. There were frequent consultations between the two morning and the two afternoon doctors in any questionable case. Of cardiac anomalies I found 2.7 per cent; the other three physicians, 1.5 per cent; two, 3.2 per cent or 2.2 per cent for 2,940 boys. In all, 136 boys were found with murmurs, but of these 64 or 45 per cent were not regarded as of chronic valvular disease. Of the 728, a history of previous treatment for heart disease was given in 2, but examination showed nothing. In 2 cases diagnosed organic disease, on weekly follow-ups, the murmurs disappeared. Whether this is a return to normal or the hearts might again give murmurs is interesting. One case of dextrocardia was discovered in 2,940. Further analysis of this group in relation to etiology, smoking and exertion should be valuable.

Each organic case was told of his present condition and careful instructions given against cardiac strain. How important this may be for his future can be seen in the great rise in cardiac deaths at 35-44 and later. In economic groups similar to ours the Metropolitan Life Insurance Company" reports death rates, per 100,000 white males, from heart disease (pericarditis, acute endocarditis and myocarditis, angina pectoris, other diseases of the heart) in its industrial department for 1929, 1 year and over, 155.8; 1-4, 7.8; 10-14, 17.6; 15-19,

26.9; 20-24, 31.7; 25-34, 46.8; 35-44, 134.4. Cahan" in a recent Philadelphia study of 1,821 high school boys up to 17 years reports 1 per cent of organic heart disease. Among school children" in different cities in this country the incidence of organic disease reported has varied from 0.63 per cent to 1.7 per cent. In elementary school children in England and Wales 0.7 per cent was found. In the Hagerstown survey Sydenstricker" gives the illness rate for diseases of the circulatory system as 9.6 per 1,000 for age 0-4; 7.6, 5-9; 15.8, 10-14; 8.3, 15-24; 12.9, 25-44; 31, 45-64.

It should be noted that, unless the chest is bared in all examined in standing, recumbent and left lateral positions or after exercise, all conditions of the heart will not be discovered or properly diagnosed. For this reason, statistics as to the prevalence of organic heart disease among students will vary. All our boys were examined with all clothing removed from chest and with facilities for recumbency. The heart disease death rate" per 100,000 population, male and female, for 1924 for age groups 10-14 was 20.5; 15-19, 26.7; 20-24, 26.6. Compared with rates of 1914, the 10-14 shows a reduction of 18 per cent, the 15-19 a rise of 8.5 per cent and the 20-24 a rise of 2.3 per cent. Figures given by the Medical Society of the State of New York" from studies by Davenport and Love on heart defects in drafted men show that of each 1,000, 45.07 showed some form of organic heart disease probably due wholly to damage of rheumatic infection, and 30.09 per 1,000 showed valvular defects. It seems apparent that just at the age of our continuation school boys much cardiac diagnostic and prophylactic investigation and advice are in order.

SPECIAL INTERESTING DEFECTS

Among other defects of special interest were flat-foot in 106 or 3.9 per cent, of which 3 cases had had arches made. None complained of any pain or disability. It would seem that in this age and group flat-foot is not a particularly disturbing condition. One hundred and ninety-six or 7.3 per cent had defective vision uncorrected by glasses, another 146 or 5.4 per cent had at some time procured glasses, but were not wearing them through negligence or fear of ridicule, another 130 or 5 per cent were corrected by glasses before our examination; in all, 17.7 per cent needed visual correction. Seven cases of acute otitis media were diagnosed and 3 of subacute and 35 of chronic found. Enlarged tonsils existed in 121 or 4.5 per cent but a diagnosis of diseased tonsils was made in only 23 or 0.9 per cent. Among 728 in Brooklyn, 4.8 per cent gave enlarged tonsils and 2.6 per cent diseased. In 100 or 3.7 per cent there were hard and mostly enlarged tonsillar glands or

nodes on one or both sides without tonsillectomy, and only 2 cases with a history of the operation.

In Brooklyn, in 728, 33 or 4.5 per cent were found with the condition without tonsillectomy and 4 cases after it. Chronic cervical adenitis was found in 259 or 9.2 per cent; in 3 cases persistence of an old tuberculous adenitis diagnosed. In Brooklyn, in 728, 3.6 per cent were found; this difference apparently coinciding with their better general nutritional condition. Of the 11 cases of undescended testicles, 7 of varicocele and 5 of hydrocele of the cord, none complained. Of the 80 cases of posture defect none was sufficiently serious to cause subjective complaint or interfere with any activity. The same applies to the endocrine disturbances and to the anemias. In 16 no exercise was taken, either because the boys' occupation was strenuous or through lack of social sense. In 2 there was over-exercise and in others there arose the question of training and reducing weight for boxing. It is a question if boys at this age and stage of development should over prolonged periods retard gain in weight. Two possible cases of benzol poisoning were followed by blood counts and inspection of work premises, but no basis for poisoning by fumes found.

Of the 1,049 smokers among 3,387 boys in Brooklyn with very few exceptions cigarettes were used, most of them inhaled, a few had smoked since the age of 6 or 7. A few were smoking 30, 40 or 50 cigarettes daily; but most of those classed as excessive smokers used 15 to 20. It should be understood that in cases of underweight, malnutrition, heart disease, poor muscular and chest development, habitus asthenicus, suspicious lung findings or anemia, any use of cigarettes at all was viewed as excessive, while in the robust even 10 or 15 cigarettes were not regarded as excessive. I found only 1 boy who was apparently lying about using cigarettes. The same applies in general to hygiene of the teeth. Some boys had apparently never cleaned their teeth all their lives; 2 boys with the dirtiest teeth worked for dental laboratories. The boy of the most untidy and unclean appearance was employed by a dyer and cleaner. Only 1 case of diabetes mellitus was found.

STANDARDIZATION OF HISTORY TAKING, PHYSICAL EXAMINATION, AND DIAGNOSIS

In such group examinations as these, the questions of standardization of methods of history-taking, of physical examination, of diagnosis and of the reliability of the diagnostic results of the different physicians are very important and most closely related. The nurse must be capable and on the alert to obtain all possible leads on subjective

complaints, previous illnesses, and operations to relieve the doctor of the need of re-questioning the boy if an important defect is found. She should know and realize the implications of deficiencies in diet, duration and amount of smoking, inhaling, number of bowel movements and its possible relation to constipation, possible heart and lung complaints, and should have ready the temperature, pulse and respiration in any suspicious case.

As soon as a number of physicians is involved, individual differences in examination and diagnosis tend to complicate results. In the Brooklyn study which I supervised with a force of three other doctors who had had no previous experience except 1 month's instruction in this work, there were such variations. Giving my findings first, the percentages of normal were 12.8, 9.5, 12.5, 8.0; of normal except unclean teeth, 12.8, 8.7, 12.0, 13.0; organic heart disease, 3.3, 1.5, 2.7, 3.2; heart anomalies; 2.7, 1.5, 2.0, 3.2; possible old pulmonary tuberculosis, 1.1, 0.38, 0, 2.0; habitus asthenicus, 0.7, 3.0, 0.8, 0.6; constipation, 2.9, 1.9, 0.7, 2.0; enlarged tonsils, 2.5, 5.9, 5.0, 5.0; diseased tonsils, 2.1, 3.9, 1.3, 3.0. It is evident that there are some distinct variations here, but it must be remembered that the type of boy varied within the school itself, and for each doctor to get an average sample there should be an equalized distribution from commercial and academic classes. But with training of the physicians in the special problems of this work and in the recognition of the usual findings in such a group reliable data are possible. Such a basis is given in the diagnosis sheets given each doctor. These sheets, covering all the systems shown in Table II,* are based on the West Side study of 2,691 boys with their 234 different diagnoses (Table III*). They do not commit the individual doctor to limit himself in his diagnostic judgment as he may add any diagnosis to the list.

At the end of each week each doctor checks on his diagnosis sheets the number of defects found. Thus the supervising physician can meet his doctors in conference at any interval he desires, and review and discuss their problems and compare the percentages of each. Certain diagnostic errors or weaknesses can be thus corrected, and such conferences have been found most valuable for the general improvement of the medical work and the ability of the individual physician. Also the habit of consultation between the doctors in any questionable case minimizes mistakes. The doctors need high diagnostic training and ability to recognize important defects and to disregard minor findings. A single pimple does not make an acne to be counted a defect.

* Available upon request to Dr. Meyers.

During this summer special work has been done by the doctors in nose, throat and cardiac clinics.

But not only is diagnostic skill needed, but a certain standardization of examination is necessary that findings may be statistically comparable and of any value. Careful note was made of appearance as it has been found that an impression of health might not be corroborated after removal of clothing or *vice versa*. Not infrequently, postural defects or underweight or other defects were found in boys of healthy aspect. Weight and height were taken with the boy stripped to waist and shoes removed. Until the genitalia were examined the boy remained thus, when the rest of the clothing was lowered. For the ears and nose, electric specula were used. The throat was thoroughly explored for enlarged, cryptic, buried or pus tonsils, but no diagnosis of diseased tonsils was made unless chronicity was established or in doubtful cases, unless a history of a related infection or repeated tonsillitis existed, or hard, enlarged tonsillar glands or nodes palpable. The glands of the neck were palpated and a general division of chronic adenitis or hard tonsillar glands made.

Teeth were examined only visually. It is certain that a dentist would have discovered many more dental conditions.

The lungs were thoroughly examined, the apices percussed, their borders outlined and compared, as also the lower posterior borders and their expansion limits related to any apical disturbance. Auscultation was particularly directed to the apices, and the infra-scapular and basal areas. In any case of finding or suspicion, temperature, pulse and respiration were noted, and further X-ray examination by the private physician or clinic instituted.

The heart was examined with the chest bared, and in erect, recumbent, lateral positions or after exercise, as necessary. Each cardiac survey was not considered complete unless it contained statements as to cardiac enlargement, murmurs, their location, character and variability, possible etiological factor, knowledge of cardiac condition, and subjective symptoms. All necessary cases were referred to the private physician or clinic for corroborative or supplementary aid in diagnosis.

The abdomen was examined in any case of constipation, of coated tongue, bad breath, and any infra-diaphragmatic pain. The liver was investigated in constipation, in heart disease, in digestive complaints, coated tongue, and bad breath. Kidneys were palpated in suspicious complaints. The genitalia were routinely examined, hernias, groin and axilla considered.

Every system shown in Table II was examined and the results defi-

nitely noted in code as normal or showing specific findings. Every effort was made to eliminate any tendency to give symptomatic diagnoses. In doubtful cases, a question mark was put after the diagnosis, the boy called for special examination again and the aid of the private physician or clinic asked for a more complete diagnosis. Slipshod diagnosis is unnecessary.

CONCLUSIONS

1. Such surveys of the 14–17-year age group, made by combined health and educational agencies, to be followed by more detailed studies of correlated findings, are interesting and valuable as they fill a gap in medical knowledge between infancy and childhood on the one hand and adult life on the other.

2. The very strong effort to enlist the coöperation of the private physician and clinic in this work, and especially the plan of the Kings County Medical Society's coöperation is an advance in the relation of public and private medicine.

3. This age group of 14–17 presents certain problems of weight, growth, nutrition, low mortality and morbidity, with lack or very low incidence of certain diseases, that are peculiar to itself.

4. Physicians in this work must be conversant with these facts and also specially trained in physical examination and diagnosis as are specialists in pediatrics.

5. Standards of physical examination, diagnosis, and recording of results are necessary, especially when numbers of examiners are involved, to procure comparable results. To this end are necessary: (1) definite training in the scope and method of the physical examination; (2) a thorough understanding of the psychology of the group; (3) a knowledge of its statistics and comparative statistics; (4) a use of the diagnostic sheets; (5) weekly checking of defects on such sheets; (6) conferences with the supervisor to check percentages of defects found and to discuss problems arising; (7) frequent consultations between the doctors during examination of any doubtful diagnosis; (8) reference to private physician or clinic for X-ray or other laboratory measures for additional or corroborative information; (9) special training in clinics, as necessary, to perfect diagnosis; and (10) realization that this work needs expert and patient diagnostic ability and that slipshod diagnosis is unnecessary and wasteful.

6. Our 14–17-year group is in a period of rapid growth in size and weight and shows great resistance to disease; the incidence of most infectious diseases is very low; heart, lung, chronic nervous disorders, gastric and intestinal conditions, and even venereal affections, are all low or largely lacking.

7. In the Manhattan study, 13.2 per cent were normal; 25.5 per cent, if we except unclean teeth as a defect. In the Brooklyn study, 12.8 per cent of 728 were normal; 25.6 per cent, not counting unclean teeth.

8. In Manhattan, on the 6-month complete reëxamination of 485 boys, the original 1,223 defects were found reduced by 583, or 47.7 per cent.

9. Only 2 cases of gonorrhea in 2,691 boys or 0.3 per cent were found in Manhattan, and only 5 or 0.1 per cent in 4,661 by 4 physicians in Brooklyn. No case of acquired syphilis was seen in Manhattan and 2 in 4,661 by four physicians in Brooklyn. Cases may have escaped the examiners, but the incidence of gonorrhea and syphilis must be low.

10. Constipation was found in 26 or 1 per cent in Manhattan, and in 2.9 per

cent in 728 and 2.4 per cent in 2,940 by four doctors in Brooklyn. The condition is relatively uncommon, and when it occurs, not severe, but usually intermittent. In Brooklyn, 97.4 per cent of the boys reported 1, 1-2, or 1-2-3 movements daily. Acute appendicitis was diagnosed only once, chronic, 3 times in Manhattan. This infrequency of appendicitis is interesting in relation to the low incidence of constipation.

11. As regards tuberculosis, there were only 2 active cases in Manhattan and 3 among 3 doctors in 2,490 boys in Brooklyn. In Manhattan, 3.3 per cent were found suspicious of possible old healed pulmonary tuberculosis.

12. As regards the heart, 1.1 per cent showed chronic valvular disease. In Brooklyn, 3.3 per cent of 728; three other physicians, 1.5 per cent, 1.2 per cent, 3.2 per cent or 2.5 per cent in 2,940 by four. In Manhattan, there were 0.4 per cent of cardiac anomalies, in Brooklyn, 2.7 per cent, 1.5 per cent, 2.0 per cent, and 3.2 per cent or 2.2 per cent for four. In Manhattan of 40 cases of murmurs, 27 per cent were not regarded of chronic valvular disease; in Brooklyn, of 136, 45 per cent were not regarded of chronic valvular disease.

13. Of 3,387 boys in Brooklyn, 1,049 or 30.9 per cent smoked and, of these 1,049, 32 per cent smoked to excess. Practically all used cigarettes and most inhaled, a few had smoked from the age of 6 or 7 years, and some were found using 30, 40 or 50 daily.

14. Despite the facts that this 14-17-year group shows comparatively low incidence of gonorrhea, syphilis, constipation, tuberculosis, diabetes, heart disease, cancer, arteriosclerosis, nephritis, and occupational disease, all these usually serious conditions will mount to their acmes during full adult and industrial life; that despite their low incidence, we still can find 6,532 defects of 234 varieties in 2,691 boys, and 7, 8, or more defects in a single boy. It becomes evident therefore that this peculiar period calls for the strict application of the modern principles and practices of preventive medicine and health education. Through a knowledge of such defects and by educational and practical medical measures we may then in these young workers discover seeds already planted for tuberculosis, heart disease and other maladies or uncover a soil waiting and ripe for future seeds, and then, like careful and expert gardeners, destroy the seeds or improve or alter the soil that the later scourges will fail to grow.

Hydrocyanic Acid Fumigation

HYDROCYANIC acid gas is our nearest approach to the ideal fumigant. Confined in inclosed spaces, quite small amounts destroy all animal life therein; but when liberated in the open air its dissipation is so rapid that it requires very large quantities to produce fatal results in human beings. . . . The gas is very penetrating. . . . It will penetrate into the center of a sack of flour in about 2 hours; and if the concentration is maintained sufficiently high, enough gas will penetrate a sack of flour in 6 hours to kill weevils. Highly porous material is very rapidly penetrated by this gas—a fact of considerable importance to fumigators, since the gas penetrates their clothing almost at once.

Penetration being merely one feature of diffusion, it is not surprising to find that the gas also rapidly passes out of materials it has penetrated. A comparatively short stay in the open air will remove most of the gas from fumigated articles. An hour's airing, for example, renders a mattress safe to sleep on, unless an excessively heavy concentration of gas has been used. Water, however, absorbs hydrocyanic acid and holds it, particularly in cold weather, so that after fumigation, moist articles require longer airing than dry ones. Ordinarily, gas absorbed by collections of water is given off so slowly that it is not dangerous; but occasionally a relatively large amount is taken up on a cold day, and when a warm day follows, the gas is then given off more rapidly. One or two accidents on ships have been attributed to gas absorbed and later released from bilge water under such circumstances. On one occasion the ship passed into the warm waters of the Gulf Stream.

. . . Foods absorb the gas, but not in dangerous quantities from the concentrations generally used in building fumigations. It is well, however, to air fumigated foods for two or three hours before eating them. Foodstuffs fumigated in fumigation chambers with high concentrations of this gas (10 to 20 oz. HCN per 1,000 cu. ft.) should be aired at least 24 hours.

Hydrocyanic acid gas is not injurious to the vast majority of the articles of commerce. In the concentrations used for ship fumigations to kill rats it is not injurious to any known material, including such delicately flavored commodities as tea and tobacco. This is a very important consideration and one of the dominating ones in the establishment of this gas as a fumigant. In heavier concentrations (10 oz. per 1,000 cu. ft.) it is injurious to delicate vegetables, such as lettuce and probably to bananas, interfering with the ripening processes. It probably would kill living foods, such as oysters, although the necessity of fumigating oysters has never arisen. Fumigated eggs usually will not hatch.

. . . Because only small amounts are required, hydrocyanic acid gas is a cheap fumigant, probably the cheapest effective fumigant. For the destruction of rats, only 2 oz. of HCN per 1,000 cu. ft. of space is required. At \$1 per lb., this amount costs \$.12½.—C. L. Williams, *Pub. Health Rep.*, May 1, 1931.

Mortality from Puerperal Septicemia in the United States*

G. E. HARMON, M. D., F. A. P. H. A.

*Department of Hygiene and Bacteriology, School of Medicine, Western Reserve
University, Cleveland, O.*

IT is well known that in practically all countries the death rates from puerperal septicemia, the largest single cause of maternal mortality, have shown little or no tendency to decline during recent years. This is remarkable in the light of present medical knowledge and of improving obstetrical practice. In a previous study¹ by the author of the course of puerperal septicemia mortality, a trend line was fitted to the data of each of a number of states. Though it was observed that these trend lines did not have the same slope, it was impossible to study the causes of this variability because of lack of data. It is possible, however, to determine whether or not the trend of the mortality from puerperal septicemia has been approximately the same for certain broader divisions of the population, namely, urban white, rural white, urban colored, and rural colored.

This was done by analyzing the data published by the U. S. Bureau of the Census in *Mortality Statistics* and *Birth, Stillbirth and Infant Mortality Statistics* for successive years from 1922 (the year in which the continuous tabulation of stillbirths began) to 1927 inclusive. All the states that were in both the death and the birth registration area for the entire period 1922-1927, were combined into a group or unit for which it was desired to assemble information:

California
Connecticut
Delaware
Illinois
Indiana
Kansas
Kentucky
Maine
Maryland
Massachusetts

Michigan
Minnesota
Mississippi
Montana
Nebraska
New Hampshire
New Jersey
New York
North Carolina
Ohio

Oregon
Pennsylvania
Rhode Island
Utah
Vermont
Virginia
Washington
Wisconsin
Wyoming

For certain divisions of the total population of this unit the total

* Read before the Vital Statistics Section of the American Public Health Association at the Fifty-ninth Annual Meeting at Fort Worth, Tex., October 30, 1930.

TABLE I

MORTALITY FROM PUERPERAL SEPTICEMIA, COMBINED STATES, WHITE POPULATION

Year	Urban			Rural		
	Total Births	Deaths from Puerperal Septicemia	Deaths per 1,000 Total Births	Total Births	Deaths from Puerperal Septicemia	Deaths per 1,000 Total Births
1922	873,288	2,279	2.61	784,663	1,373	1.75
1923	896,292	2,508	2.80	776,431	1,363	1.76
1924	921,738	2,451	2.66	788,527	1,324	1.68
1925	898,943	2,462	2.74	757,993	1,201	1.58
1926	883,164	2,340	2.65	729,384	1,221	1.67
1927	889,169	2,358	2.65	729,782	1,149	1.57

births (live births and stillbirths) and the corresponding number of deaths from puerperal septicemia were obtained, suitable combinations being made where necessary, from the government publications for each year of the period 1922-1927. With this information, death rates were next calculated. These were expressed as the number of deaths from puerperal septicemia per 1,000 total births, a method discussed and advocated by both Howard² and Hemenway.³ The class "total births" includes, of course, both living births and stillbirths.

The results of this analysis are presented in Tables I and II and Figures I and II. As defined by the U. S. Bureau of the Census, "urban" is descriptive of the population living in cities which had 10,000 inhabitants or more in 1920, and "rural," of the population living in places which had less than 10,000 inhabitants in 1920. It

TABLE II

MORTALITY FROM PUERPERAL SEPTICEMIA, COMBINED STATES, COLORED POPULATION

Year	Urban			Rural		
	Total Births	Deaths from Puerperal Septicemia	Deaths per 1,000 Total Births	Total Births	Deaths from Puerperal Septicemia	Deaths per 1,000 Total Births
1922	46,727	220	4.71	81,332	223	2.74
1923	52,238	267	5.11	81,110	225	2.77
1924	59,270	264	4.45	82,599	254	3.08
1925	59,780	300	5.02	81,479	231	2.84
1926	60,040	277	4.61	81,566	189	2.32
1927	62,177	320	5.15	79,915	225	2.82

FIG. I. DEATH RATES FROM PUERPERAL SEPTICEMIA, COMBINED STATES, WHITE POPULATION, 1922-1927.

FIG. II. DEATH RATES FROM PUERPERAL SEPTICEMIA, COMBINED STATES, COLORED POPULATION, 1922-1927.

will be seen by a study of these tables and figures that there certainly has been no tendency for the rates to decline in the urban white, urban colored, and rural colored divisions of the population. For the rural white division, however, the rates have had a very slight tendency to decline, but in view of the shortness of the period studied this is probably without significance. (The rates for the rural part of the population have been always less than those for the urban part. This is true for both the white and the colored group. The death rates for the colored population have been always higher than those for the white population in both the urban and rural sections.)

Attention will now be directed to another aspect of the problem. Is there any association between the magnitude or trend of the death rates and aggregation of population as judged by the size of city in which people live? In tabulating the data for the urban population of the combined states with the addition of Washington, D. C., to obtain some information upon this point, it seemed preferable to make the classification of cities as to size depend upon the number of total births recorded in 1922 rather than upon the total population in 1920. Accordingly, those places which had a population of 10,000 or more in 1920 were classified into 3 groups: all having fewer than 700 total births in 1922; all having from 700 to 2,000 total births in 1922; and all having 2,000 or more total births in 1922. The results are set forth in Table III. It will be seen that there has been no definite tendency for the death rates for any of these 3 sub-divisions of the combined urban population to decline. (The rates, however, tend to be lowest in the group of large cities.)

TABLE III

MORTALITY FROM PUERPERAL SEPTICEMIA, COMBINED STATES, TOTAL URBAN POPULATION

Year	Cities Having Fewer than 700 Total Births in 1922			Cities Having from 700 to 2,000 Total Births in 1922			Cities Having 2,000 Total Births or More in 1922		
	Total Births	Deaths from Puerperal Septicemia	Deaths per 1,000 Total Births	Total Births	Deaths from Puerperal Septicemia	Deaths per 1,000 Total Births	Total Births	Deaths from Puerperal Septicemia	Deaths per 1,000 Total Births
1922	157,356	458	2.91	156,811	477	3.04	615,414	1,594	2.59
1923	163,505	493	3.02	165,274	569	3.44	629,225	1,751	2.78
1924	169,599	445	2.62	173,291	570	3.29	647,851	1,753	2.71
1925	165,631	510	3.08	169,245	566	3.34	633,398	1,723	2.72
1926	163,258	495	3.03	166,276	503	3.03	623,033	1,647	2.64
1927	165,050	497	3.01	168,299	489	2.91	627,488	1,726	2.75

These findings may be summarized by the statement that, for the period studied, with the possible exception of the rural white division, the death rates from puerperal septicemia have not declined in any of the divisions of the population considered, and furthermore that the rates for each division have remained remarkably constant.

Septic Sore Throat

AN explosive outbreak of septic sore throat involving over 450 cases, with 4 deaths; is reported. The epidemiological evidence establishes that the source was infected milk from one dairy.

The attack rates in households exposed vary from 38 per cent in the 10-14 year old groups, to over 60 per cent in the group of 20-30 years. The vast majority of infected families showed multiple cases. Suggestive but inconclusive evidence is given that the cow was infected by human carriers of the causative agent of scarlet fever.

The epidemic was controlled by stopping the sale of unpasteurized milk.—McKay, A. L., and Hardman, R. P., A Septic Sore Throat Epidemic, *Canad. Pub. Health J.*, May, 1931.

Immunization of Dogs against Rabies by the One-Injection Method*

H. W. SCHOENING, V. M. D.

Pathological Division, U. S. Bureau of Animal Industry, Washington, D. C.

VACCINATION as a prophylactic against rabies in dogs, developed by the Japanese investigators, Umeno and Doi,¹ has had extensive use in the United States following its introduction into the country by Eichhorn and Lyon, in 1922.² Some idea of this can be gathered from the fact that, from 1923 to July 1, 1930, approximately 2,000,000 doses of this type of vaccine have been prepared by commercial houses operating under Federal Veterinary License.

The original vaccine of Umeno and Doi was a fixed virus attenuated by phenol and contained 20 per cent of brain tissue. As this contained living virus and was found capable of producing the disease,³ a feature highly objectionable in a prophylactic vaccine, its use was discontinued and its place taken in recent years by those killed by chemicals or rendered avirulent to such an extent as to be incapable of producing the disease when injected subdurally into rabbits.

There has been considerable discussion as to the merits of the one-dose vaccine and a variety of opinions have been expressed. The points to be considered in evaluating the vaccine are: (1) Does it immunize? (2) Is it safe? (3) How long does immunity last?

Does it immunize? The vaccines considered are those in use in the United States at present. There are two commercial types, one phenol treated, and the other chloroform treated, both of which are either killed, or are avirulent to such an extent that they cannot produce the disease under the most severe test—subdural injection into rabbits. It is held by some that a dead virus has no immunizing properties and that a vaccine consisting of a dead virus is impotent. Animal inoculation is the only test for viability now available and until new methods are at hand a differentiation cannot be made between a virus that is destroyed and one that has been rendered completely avirulent, but is still living.

The phenol-treated vaccines contain from 10 to 20 per cent of brain

* Read before the Laboratory Section of the American Public Health Association at the Fifty-ninth Annual Meeting at Fort Worth, Tex., October 29, 1930.

tissue, while the chloroform-treated contain $33\frac{1}{3}$ per cent brain material.

Experimental tests in 1928-1929⁴ showed that of 12 dogs treated with the phenol vaccine and later exposed to street virus by intramuscular injection, 5, or about 40 per cent, died of rabies, while of 11 controls, 9, or about 80 per cent, contracted rabies—a decided difference in favor of the vaccinated dogs. It was also noted that deaths of the vaccinated dogs occurred among those treated with particular lots of vaccine. In other words, while the number of cases was small there appeared to be a difference in potency in lots of vaccine prepared in the same manner. It would seem that phenol vaccines in general are capable of producing a reasonable degree of immunity in dogs, but that failures are to be expected at times.

Of practical importance in the field use of the vaccine is the question of the plurality of types of the virus of rabies. Are there types that are immunologically different? The fixed virus from which vaccines are made in this country is a single strain, found on inquiry some years ago to have had its origin in the Pasteur Institute of Paris, France. Do types of street virus exist against which the vaccines made from the standard fixed virus cannot immunize? It is accepted that there is a marked variation in the virulence of different strains of rabies virus, and while the unity of rabies virus is generally held, suggestive evidence has been presented at times to indicate the possibility of the existence of more than one type.⁵ The writer encountered a strain several years ago against which apparently little immunity in dogs could be produced. This has been studied in the laboratory and possesses a marked characteristic not seen with other strains of street virus—the amazingly great number of Negri bodies regularly found in smear preparations from the hippocampus. This characteristic has been preserved over a period of years and after a large number of passages in the rabbit. Further immunity studies with this strain are contemplated.

Failures of the vaccine in the field have been noted. These can be explained on the basis of the failure of the vaccine to induce an immunity or to exposure of the animal to a type of street virus immunologically different from the standard fixed virus. Until proof has been produced experimentally as to the plurality of the rabies virus, this question must remain unsettled.

Experimental work on the potency of chloroform-treated vaccines has been highly encouraging. In 1929⁴ we showed that of 9 dogs treated with this type of vaccine, all survived exposure to a street virus injected intramuscularly which was sufficiently virulent to cause rabies

in 11 of 13 control dogs. This product has only recently been placed on the market and no data are available on its efficacy under field conditions. Recent work by Kelser with the chloroform-treated vaccine showed a high degree of potency when tested on rabbits.⁵

Is the vaccine safe? The phenol-killed vaccine, if prepared properly, is incapable of producing rabies, as it must before release be shown not to contain virus capable of producing the disease on subdural injection in rabbits. However, there is a certain element of danger that should be recognized. This is a paralysis somewhat similar to that seen occasionally in man following antirabic treatment. In man it has been noted that paralysis is less apt to occur when vaccines which have been attenuated or killed by phenol are used. It is believed probable from the number of cases reported experimentally⁶ that the dog is more susceptible to vaccination paralysis than man, although exact figures are lacking. Most of the cases of paralysis appear from within a few days to several weeks after vaccination and the majority of cases result in complete recovery, although the termination may be fatal. Cases of paralysis have been noted in experimental work and also following the field use of vaccine.

The chloroform-treated vaccine, like the phenol-treated, if prepared properly cannot produce rabies. Experimentally, no cases of paralysis have been observed in 30 dogs vaccinated with this product by the writer. The vaccine has been used on approximately 150 dogs at one of our army posts to date with no unfavorable reactions. Just how this vaccine will act under field conditions remains to be seen.

There is a possibility that vaccination may produce for a short period a temporary negative phase during which a dog may be more susceptible to infection than one not vaccinated. This was suggested by limited experimental work reported in 1928.⁷ It would appear to be a safe procedure to keep vaccinated dogs in quarantine for 2 or 3 weeks to observe the effects of vaccination and to keep them from possible exposure until immunity has become established.

How long does immunity last? Experimental data have been presented by several workers which indicate that the original Japanese vaccine induced immunity that persisted from some months to 1 year, and that it was apparent after 1 month. Data in respect to phenol-killed vaccine are quite meager. The writer encountered 1 dog which resisted infection 1 year after vaccination. Immunity should not be considered in any event to last more than 1 year, and in some cases it may endure for a shorter time.

No data on chloroform-treated vaccine are available beyond 4 months.

DISCUSSION

It would appear that phenol-killed vaccines are capable of producing immunity in dogs when given in 1 dose, but also that failures of this type of vaccine are to be expected, and a false sense of security should not obtain because of vaccination.

The possibilities of post-vaccinal paralysis with this type of vaccine should be recognized and no absolute assurance should be given that no harm to the dog will result.

From the data available it appears that the chloroform-treated vaccine is superior to the phenol vaccine in both potency and safety, but final judgment must await its use in the field.

Many favorable results have been reported with the use of vaccination in conjunction with other standard control measures in combating outbreaks of rabies in the field. The reduction of the susceptibility of a dog population to rabies infection is a step forward in the control of the disease, but the rigid enforcement of such standard measures as the destruction of stray dogs and quarantine is absolutely necessary for the solving of the rabies problem.

Comfort in Temperature and Humidity

THE record shows that in the experiments as a whole from 91 to 97 per cent of the group found 70° F. comfortable, irrespective of the humidity. . . . While the optimum humidity seemed to be 55 to 60 per cent, it may be concluded that in an auditorium kept at the standard temperature of 70° F. variations in humidity between the limits used, which are those that ordinarily prevail indoors in temperate climates under winter conditions, make but little difference in the sense of comfort and well-being of the occupants. It is doubtful, therefore, whether there is any justification for the installation of expensive equipment for the control of humidity. For such conditions the dry bulb temperature is the important standard to maintain, together with provision for the renewal and adequate movement of the air.—W. H. Howell, *Science*, Apr. 24, 1931, p. 455.

Birth Records of Illegitimates and of Adopted Children*

Part I

SHELDON L. HOWARD

Illinois State Registrar of Vital Statistics

Part II

HENRY B. HEMENWAY, M. D., F. A. P. H. A.†

*Medical Assistant Registrar, Vital Statistics Division,
Illinois Department of Public Health, Springfield, Ill.*

SEEMINGLY no better conception of the existing conditions surrounding illegitimacy in this country, and of the more or less progressive legal steps taken by our various states in connection therewith, can be obtained for consideration, than in Dr. Marietta Stevenson's "Analysis and Tabular Summary of State Laws Relating to Illegitimacy in the United States, in effect January 1, 1928, and the Text of Selected Laws," as set forth in 1929 in "Chart Number 16" of the Children's Bureau of the U. S. Department of Labor.

The pithy first paragraph of this article summarizes most effectively the present status of unlawfully born children:

Birth statistics are incomplete and no one knows exactly how many children are born out of wedlock in the United States each year. It was reported, however, that 55,134 children were born out of wedlock in the states included in the registration area in 1927 (exclusive of California and Massachusetts, for which illegitimacy statistics were not available). The population of the registration area exclusive of these states comprised more than two-thirds of the population of the United States. It is known that the percentage of illegitimate births is much higher in some states than in others, higher in the city than in the country, and higher for the negro than for the white race. Many of the mothers are pathetically young and are handicapped oftentimes in other ways. It is estimated that about half the mothers are under 20 years of age, and a large proportion of the remainder under 25. The fathers also are quite often mere boys. Considering the problem of illegitimacy from the standpoint of the child, his mother, his father, and society, the need for humane, comprehensive, and constructive laws for safeguarding the rights and insuring the fulfillment of the obligations of the four parties interested becomes clear.

* Read before the Vital Statistics Section of the American Public Health Association at the Fifty-ninth Annual Meeting at Fort Worth, Tex., October 30, 1930.

† Deceased.

Dr. Stevenson's treatise is a noteworthy accomplishment. It succinctly lays before us the *legal gains* which have already been made by the states in behalf of this unfortunate class along the lines of rights and obligations of parents, action necessary to establish paternity and legitimation, and child's rights of maintenance and inheritance or succession. It contains, as well, some very timely and inspiring comments which should generate within all the determination to do our utmost to insist on equally rational treatment of the inhumane features of the problem, which, under present custom, continue to exist as hindrances to the well-being of each illegitimate child long after all statistical requirements are satisfied and all legal redress secured.

Doubtless many of us directly concerned with the work of registration of births, under statutes patterned closely in accordance with the so-called "Model Law," experienced a hopeful thrill as we came in contact with Dr. Stevenson's analysis and read these words:

The old unscientific point of view, evidently inspired by moral indignation, expressed itself in legislation meant to punish and stigmatize the unfortunate child and his mother. *The modern aim is instead to protect and care for the child.* Much of the legislation is in an experimental stage, but certain tendencies are discernible, *the result of a growing feeling that the child born out of wedlock unavoidably suffers enough disadvantages without emphasizing these by legislative discrimination.*

In that paragraph, it seems, is the keynote—the guidon which we should follow, until the sorely needed modern legislative measures suited to the "growing feeling" are enacted, and are accorded liberalized administration.

Registrars, as birth record keepers, from a statistical standpoint, know that the factor of illegitimate births has no inconsiderable bearing on the distortion of their returns with respect to bona fide area of inception. A high percentage of such births are recorded at places other than the "usual abode" of the mother. The very character of these births has a marked tendency to inhibit their being reported at all. Would not legal provision for the recording of foundlings under a plan, similar to that mentioned further on, improve the "Degree of Completeness of Birth Registration"?

So much for the statistical aspects—but what of such cases in relation to their individual rights as members of society?

Turning again to the Stevenson analysis, we read that at a regional conference of the Children's Bureau, in 1920, "The duty of the State to protect the interests of children born out of wedlock was recognized and affirmed," and "the numerous laws defining the relationship of the

illegitimate child to his parents and placing a duty of support upon the father, especially laws passed in the last 15 years, are indications of a changing social attitude." So far, so good—the legal rights of these unfortunate children, as they became apparent to the public mind, have been fairly well established. But what of their social rights?

Unquestionably, the establishment of the illegitimate child's rights was, and still is, the first consideration—it must so be for the protection both of the child and the State, especially in cases where one or both parents are known. Naturally and logically then, the adjustment of the legal phases of such cases has occupied the major portion of the time and effort of child welfare bureaus, as is reflected by the character of the enacted laws. Under the old order of things such legal adjustment was sufficient, and accordingly helpful legislation was not developed further.

The old order has given way to the new, and although formerly the statements of the child or its parents as to name, age, and relationship were accepted; now the presentation of a duly authenticated birth certificate has become an almost universal prerequisite for admittance to school or employment, or for foreign travel. Small barrier, this, to the legitimate child or his parents who have merely to apply for a certified copy or a transcript of the birth record—but what of the illegitimates, adopted children, and foundlings?

These and their foster parents or guardians are apt to find themselves in a predicament, for if they are successful at all in securing a record of the birth, that very act may carry with it most distressing revelations likely to permanently impair otherwise peaceful mental conditions and happy lives. Where can we find the remedy?

Again we are encouraged by the hopeful rays which appear to light the pathway of our search when we note from the "Analysis" a tendency on the part of some states, such as Iowa and North Dakota, to minimize the broadcasting of distressing trial details by statutory exclusion of the public, or vest the power of such exclusion, as in New York and Minnesota, in the trial judges.

We are further heartened by finding among the Statutes of Colorado (Laws of 1925, ch. 133—Maternity Hospitals) that the divulgence or disclosure of the contents of any records relating to illegitimate children is prohibited.

We are convinced that our attitude is right when we read in Section 7 of this Colorado Act:

That this chapter shall be liberally construed with a view to effecting its purpose which is primarily to safeguard the interests of illegitimate children, and those

of undetermined legitimacy born in maternity hospitals as herein defined, and secure for them the nearest possible approximation to the care, support and education that they would be entitled to receive if born of lawful marriage, which purpose is hereby acknowledged and declared to be the duty of the State.

In the words "secure for them the nearest possible approximation to the care, support and education that they would be entitled to receive if" lies the sought for antidote. True, it is there only in embryo as it were, not specifically expressed by the addition perhaps of the words "and rights of citizenship," following the "care"—"support"—"education" benefits now provided. Nevertheless it is inconceivable that the Colorado Legislature could have had other intent than that these unfortunates should be equally vested with the "inalienable constitutional rights" of "life, liberty and the pursuit of happiness," as are children legitimately born. Now, in the light of dawning consciousness of the social factors mentioned, and in the discernibly favorable crystallization of public opinion indicating that the time is ripe for action, how can this be accomplished so thoroughly, humanely and sensibly that it will practically insure for these children immunity from unnecessary embarrassment, pain, or disgrace, from the time of the launching of their individual careers—their advent into school or employment?

Clearly it is most desirable to secure such legislation as will authorize and enable bureaus of vital statistics or other custodians of birth records to include among their functions, subsequent to the taking of required statistical data, the suppression of such original records or statements of facts as may have become nullified, readjusted or supplanted through legal procedure accomplished after the time of registration.

As members of this Association primarily concerned in the record keeping which is a counterpart of birth registration, both in our respective states and at the U. S. Bureau of the Census—we seem to be, logically, the missionaries who should bring about the rectification of the existing evils. If we are registrars of vital statistics, ours is a dual rôle—on the one hand, as statistical craftsmen we must insist on the accuracy of the basic data, but on the other, in serving the public we must do all possible to furnish only such copies of birth records as will best promote the welfare of the persons concerned.

Due to our unique positions, we are best qualified to act. It is signally fitting, therefore, that we should take the lead in this matter, and accordingly the following plan of my associate and collaborator is respectfully submitted for consideration:

Legitimation, Adoption and Foundlings

Registrars of vital statistics are guardians and trustees of the interests of the people. This is peculiarly true in relation to records of birth.

In drafting the "Model Law" for the registration of births, stillbirths and deaths, three very important classes of cases were apparently entirely overlooked, namely cases of legitimation of birth, those of adoption, and those of foundlings. In consequence many children are often unjustly stigmatized as bastards, and the birth records of adopted children frequently cannot show their legal names by adoption. In many cases of adoption there is also the stigma of bastardy. A foundling has no birth record.

When a child begins to attend school in many states he is required to present evidence that his birth has been recorded. A certificate for "John Jones" is not satisfactory in the case of a boy legally known as "John Miller." It must be accompanied with other evidence showing illegitimate birth, or legal adoption, or both. This not only is a direct injury to the child, and a cause of embarrassment for parents, but seriously interferes with the placing of children in desirable homes.

The statutes of the states relative to these subjects vary. Minnesota, for example, provides for reporting cases of legitimation to the vital statistics office; but in a certified copy of birth record, it does not prohibit the certification of illegitimate birth.

The statutes of Illinois may be considered typical for the country at large, and are therefore taken as the basis for this presentation, in order that specific sections may be cited. With slight changes in wording the recommendations would apply for many other states.

A common law marriage is not recognized in Illinois. It is illegal, and births from such unions are therefore illegitimate. Chapter 89, Smith-Hurd Statutes of Illinois, Section 17(a), however, provides that although the marriage may have been contrary to law, if the parents "have attempted to contract and be joined in marriage, and some form of marriage ceremony recognized by law has been performed in apparent compliance with the law in relation to marriage," the issue of such union "is hereby made legitimate and may take the name of the father, though such attempted marriage is declared void or might be declared void for any reason."

Chapter 39, Smith-Hurd Statutes (relative to descent of property), in Section 3 says:

An illegitimate child, whose parents have intermarried and whose father has acknowledged him or her as his child, shall be considered legitimate.

Chapter 17 (relative to Bastardy) in Section 15 provides:

If the mother of any bastard child, and the reputed father shall at any time after the birth intermarry, the said child shall, in all respects, be deemed and held legitimate and the bond aforesaid be void.

There is no provision in the statutes for reporting such acts of legitimation to the vital statistics office, and the Attorney General has held that the Registrar has no authority to accept such documents when offered, nor to permit a change in the record of illegitimacy.

The Illinois Vital Statistics Act, Chapter 111½, Section 48, prohibits that a certificate of birth for an illegitimate child shall

. . . contain the name or other identifying fact relating to the father or reputed father or to the mother thereof, without the consent of said father or reputed father to the use of his name, nor the use of the name of the mother without her consent to the use of her name.

Under present statutes the birth registration of illegitimates is therefore frequently very defective from a statistical standpoint.

It is therefore suggested that vital statistics acts be amended by providing that in case an affidavit is presented to the State Registrar, signed by the father, acknowledging the paternity of the child, and the fact of place and date of his legal marriage to the mother of the child, a new certificate of birth may be filed which shall be considered as the record of birth; and it should further provide that the original certificate of illegitimacy and the aforesaid affidavit shall be placed in a sealed package, only to be opened under orders from a court of record. It should also be provided that in case of marriage of the parents of an illegitimate child before a certificate of birth has been filed, such child shall be considered as legitimate at birth.

Chapter 4 (relative to Adoption) provides in Section 3 that on the filing, hearing and granting of a petition for adoption in the proper Court

. . . a decree shall be made, setting forth the facts and ordering that from the date of the decree the child shall, to all legal intents and purposes, be the child of the petitioner or petitioners, and may decree that the name of the child be changed according to the prayer of the petition.

This section should be so amended as to require that when the name of the child is changed, the clerk of the court shall send an attested copy of the decree to the State Registrar of Vital Statistics. Then on receipt of such copy the State Registrar shall cause to be made a new record of the birth in the new name, and with the name or names of the adopting parent or parents. He shall then cause to be

sealed and filed the original certificate of birth with the decree of the court, and such sealed package shall only be opened upon the demand of said child, or his natural or adopting parents, or by the order of a court of record.

The state has a peculiar responsibility relative to foundlings. The state has not fulfilled its obligation when it provides for their care, food, and clothing. It must also provide for proof of citizenship and age. At present there is no statute in Illinois which requires or even authorizes a legal registration of foundlings. Birth certificates are impossible. When such a child should enter school, attempt to work, try to register as a voter, or require the protection of the government as a citizen, how is he to establish his rights? This question is of greater importance since the registration of all births has been required by law. It seems, therefore, that a statute should be enacted which will require that the *finding* of an unknown child shall be immediately reported to the local registrar of vital statistics; such report to show the sex and color of the child, the date and place of finding the child, and the name of the person or institution with whom it is placed. The city, village, township, or road district in which the child is found should be known as the place of legal birth. Inasmuch as the date of birth is unknown, the report should state such date as nearly as can be determined, and the date so given should be known as the legal date of birth.

The person or institution with whom the child is placed for care should be required to give it a name, and report the same to the local registrar. The "Certificate of Finding" should then be sent to the state registrar, and there filed. If the child should later be identified, and a certificate of birth be found or obtained, such fact should be reported to the state registrar, and indorsed upon the "Certificate of Finding," with citation to the certificate of birth.

RESOLUTION ADOPTED BY THE VITAL STATISTICS SECTION

RESOLVED that in the opinion of this Section, methods should be devised and made legally effective for the correction of birth records of children legitimized, and of adopted children, and also for the registration of foundlings; and be it further

RESOLVED that a committee of five be appointed by the chair to consider and report, at the next Annual Meeting of this Section, the advisability of a uniform or "standard" system for:

1. Acts correcting birth records of illegitimate children subsequently legitimized
2. Acts regulating birth records of children legally adopted
3. Acts for the making of birth records of foundlings

Fungus Infections of Skin of Industrial Workers*

ROBERT T. LEGGE, PH. G., M. D.

Professor of Hygiene, University of California, Berkeley, Calif.

THE medical and public health professions in this country must awake to the realization of the importance of mycotic infections as a causative agency in disease. In a previous paper¹ a plea was made that at least every state hygienic laboratory should have on its staff a trained mycologist to aid physicians, and sanitarium and hospital authorities in the identification and diagnosing of fungus diseases.

Mycotic infections are not strictly confined to dermatology, but are an important factor in internal medicine; the incidence of morbidity being higher among the industrial group. One need only consult the literature to find blastomycotic infections among paper workers, sporotrichosis in gardeners and malt handlers, aspergillosis of the lung common in French pigeon feeders, and actinomycosis among herdsmen and farmers.

On the Pacific Coast, many contributions have been published of fungus diseases among industrial and agricultural workers. Some 134 cases of coccidioidal granuloma² have been reported in California, particularly in and about the San Joaquin valley. Many of these victims were engaged in out-of-door occupations, which suggests that the infection may be present in the soil or upon vegetation. This seems the more probable, as H. J. Templeton's case was a cotton mill hand who probably contracted coccidioidal granuloma from cotton grown in this valley. There was another case of coccidioidal granuloma of the hand following an injury by wire.

On account of the saprophytic nature of the genus *Penicillium* which is so common in nature, workers in out-of-door vocations may contract a pulmonary disease having a mucopurulent expectoration, often bloody, with fever and emaciation; a typical picture of tuberculosis, with the exception of being negative for tuberculosis bacillus. Three such cases came in to our service, which were proved by mycological examination to be broncho-penicilliosis, and which made un-

* Read before the Industrial Hygiene Section of the American Public Health Association at the Fifty-ninth Annual Meeting at Fort Worth, Tex., October 27, 1930.

eventful recoveries through the administration of iodides, and the use of autogenous vaccines made from the sputum.

Kingery and Thienes reported, before the American Dermatological Association in 1924, a mycotic paronychia which appeared among workers in fruit canneries of the Northwest. During the pear season the incidence is marked, running as high as 33 per cent. This has been commonly known as "fruit poisoning." There is a marked paronychia, characterized by an inflammatory reaction, pain, swelling, and loss of finger nails. Frequently there is maceration, and cracking between fingers, and vesiculation on the hands and forearms.

H. Sutherland Campbell, of Los Angeles, has observed that certain workers whose fingers came in contact with the pulp or juice while engaged in squeezing cull oranges in the manufacture of orange juice acquired a fungus infection producing a paronychia. The yeast-like organism supposed to cause this infection belongs to the *Mucoraceæ* family.

Recently R. H. M., a painter, was referred to me. He had a severe dermatosis of both hands, and stated that it was due to turpentine. He made application for compensation to the State Insurance Fund, claiming it was an occupational disease. Upon microscopical examination of skin scrapings it proved to be epidermophytosis. Undoubtedly this case was aggravated by the solvents employed in mixing paints, and still may have been a secondary fungus invasion superimposed on a traumatized skin from a coworker carrier, or from his own toe focal infection. Such cases require the keenest judgment on the part of the physician in order to render a fair and impartial decision.

From an industrial point of view, every suspicious skin irritation warrants a careful routine inspection for a possible fungus infection. On account of the universal prevalence of foot ringworm, one can readily see how other parts of the body can be infected, independent of the patient's occupation. We found that 10 per cent of the university students infected with tinea cruris had superimposed a *Trichophyton interdigitale* fungus, undoubtedly carried by the towel when drying the feet and later the groin. Due to this fact, as a public health measure, all bathers when using a towel should always dry the body first and the feet last; the towel then being sent to a steam laundry.

Upon the return of the U. S. Volunteers from the Philippines in 1899 the so-called dhobie itch or "Shanghai foot" was a common infection among the troops, causing much disability, and was a factor in disseminating foot ringworm in this country.

Ringworm of the feet is the most common fungus disease in America today, not only affecting workers in bathhouses and gymnasiums, but also students, clubmen, and the general laity who frequent common showers, swimming pools, hotels, and golf and athletic clubs.

At the University of California during the fall semester, 1928, when the compulsory physical examination was conducted for all freshmen, it was found upon careful examination of the toes that $51\frac{1}{2}$ per cent of the men and $15\frac{1}{3}$ per cent of the women were infected with ringworm. The principal fungus responsible for this common infection is *Trichophyton interdigitale*. Bonar, the mycologist working in our research group, has observed that when replants of a single spore in a culture are made, the resulting growth when aged sufficiently may change in character, making it difficult to identify the morphology of the different types of moulds reported by investigators. Two varieties have been definitely studied that differ in morphology and spore formation. We have been able to determine that the fungus will grow readily in human skin and hair, and in fact any animal tissue, such as wool, silk, bone, horn and leather, and only sparingly in wood, providing some favorable protein is present. We have not been able to grow on media the *Trichophyton interdigitale* from scrapings from shower floors on account of the abundant growth of funguses that crowd out the pathogenic moulds. We are convinced however by the saprophytic nature of the fungus that it multiplies and continues to keep up infection, by the countless skin scales and hairs that are cast or washed off the body during the process of taking a shower or disrobing. The next bather picks up the organisms on his feet, and this is the method of contracting the disease.

The laboratory investigator may be able with certain fungicidal chemicals to destroy the mycelia and spores *in vitro*, but when they are applied clinically it is a different matter entirely, as they may be destructive to the tissues or only affect the epidermis superficially. We have removed thousands of pieces of skin from infected individuals, and proved clinically by culture and microscopic examination that the funguses were present. These bits of infected skin can be soaked in alcohol and sterilized, which will destroy the bacteria and mycelium present, but when they are washed and placed in a plate of sterile Leonians' agar at room temperature, mycelium will appear in a few days, definitely proving that the spores are deeply imbedded in the tissue, and demonstrating the uselessness of many ointments and lotions that are in use therapeutically.

With this important knowledge of the spores' habitat in the living

infected skin, we have tried to determine some fungicidal method for their destruction. For the past 2 years some 26 chemical agents known to dermatologists, mycologists and experimental workers have been studied in our laboratory and clinic, and the ideal specific has not yet been discovered. Among the halogens, iodine in glycerine is efficient; of the stearoptens, thymol 1 per cent or 2 per cent ranks pre-eminent; of the acids, salicylic, benzoic and sulphurous are useful; and among the dyes, crystal, first introduced by the author, gives much promise.

As the result of our researches in cultivating ringworm fungus on all types of animal tissue, such as wool, silk, leather, etc., we advise that all gymnasium clothing should be of cotton or linen, and socks and jock straps of cotton. Woolen socks favor the growth of the funguses, and as laundries do not boil woolen socks on account of the shrinkage a constant source of infection is maintained.

We have demonstrated that a temperature from 75 to 100° C. will destroy the *Trichophyton* spores; which fact is of great public health value in prescribing laundry ordinances.

Three other important problems confront the sanitarian: The first is disinfection of shoes worn by patients who have ringworm; leather, being animal tissue, is a constant nidus for spore multiplication and consequently re-infection to the wearer. We have tried dusting the inside of the shoes with sulphur, which is an excellent fungicide, but it may cause a dermatitis. On account of its lethal and penetrating qualities, 1 per cent thymol dissolved in alcohol or gasoline and poured into shoes, then allowed to drain and dry, seems to be very effective.

The second factor is the disinfection of floors, runways to pools and showers; a most difficult problem. To secure a cheap, reliable, noninflammable and nonodorous fungicide that will not corrode the floors and tiles, and at the same time be nonirritating to bare feet, has been our hardest problem. Every hotel, club and swimming pool manager is intensely interested in securing an ideal disinfectant. Bichloride of mercury 1:1,000 which *in vitro* will kill spores of *Trichophyton interdigitale* in 3 minutes could be added to a floor cleaning compound or solvent, as an effective economical fungicide. Third, to the remote corners of the earth should be broadcast this slogan to prevent ringworm of the feet—

NEVER PLACE THE BARE FEET UPON THE FLOORS
OR SHOWER BATHS IN PUBLIC PLACES.

At the University of California⁵ when the women students' feet were examined upon matriculation, 15 per cent of the freshmen en-

trants had ringworm. On account of the rigid rule that all students must wear rubber bathing slippers when in the gymnasium, pools and showers, the incidence of infection had only increased 2 per cent a year later when reëxamination took place.

An important procedure is suggested in the interest of public health—that when a person uses a public shower and sandals are not available, he step on heavy newspaper or towel when bathing and also when drying the feet.

Hotel keepers are now supplying paper slippers for their guests and the time is ripe for swimming and athletic club managers to supply rubber or wooden sandals for their customers, which after being worn are sterilized by boiling. Such suggestions as these offer the best measures to prevent one of the most important infectious diseases that confront our profession today.

Sir Andrew Balfour

IT seems to me fitting before beginning this lecture that I should also refer to the greatly lamented decease of my predecessor as Hastings lecturer, Sir Andrew Balfour. A year ago Sir Andrew Balfour lectured on the subject which reflected his life's work and interests—namely, 'Health and Empire.' Balfour was of the salt of the earth, capable and efficient in all he undertook, whether it was playing football for Scotland, administering in unhealthy tropical lands, or building up and directing the London School of Hygiene. With these qualities of distinction he was generous and open-hearted in all he did. Hastings and Balfour had much in common, and it is curious to note that just as Hastings, two years before he died, finished off a lecture with these words: 'England, may thou be destined to spread a knowledge of Sanitary Science over the globe: to set an example to other people of obedience to physical laws laid down by the Almighty: and, in the words of Milton's magnificent poem, "to lead the nations in the way of life,"' so also one of Balfour's last duties was to deliver his lecture on 'Health and Empire.'—Edward Mellanby, M.D., *Brit. M. J.*, Mar. 21, 1931, p. 1387.

Training and Personnel*

FOR several years the Committee on Training and Personnel has collected data concerning students registered in schools of public health and the public health degrees granted. The following is the report for the calendar year 1930.

TABLE I

NUMBER OF STUDENTS ENROLLED AND PUBLIC HEALTH DEGREES OFFERED AND CONFERRED IN 1930, IN COURSES REQUIRING AT LEAST ONE YEAR OF RESIDENCE AND LEADING TO A PUBLIC HEALTH DEGREE

Sir Andrew Balfour

IT seems to me fitting before beginning this lecture that I should also refer to the greatly lamented decease of my predecessor as Hastings lecturer, Sir Andrew Balfour. A year ago Sir Andrew Balfour lectured on the subject which reflected his life's work and interests—namely, 'Health and Empire.' Balfour was of the salt of the earth, capable and efficient in all he undertook, whether it was playing football for Scotland, administering in unhealthy tropical lands, or building up and directing the London School of Hygiene. With these qualities of distinction he was generous and open-hearted in all he did. Hastings and Balfour had much in common, and it is curious to note that just as Hastings, two years before he died, finished off a lecture with these words: 'England, may thou be destined to spread a knowledge of Sanitary Science over the globe: to set an example to other people of obedience to physical laws laid down by the Almighty: and, in the words of Milton's magnificent poem, "to lead the nations in the way of life,"' so also one of Balfour's last duties was to deliver his lecture on 'Health and Empire.'—Edward Mellanby, M.D., *Brit. M. J.*, Mar. 21, 1931, p. 1387.

Training and Personnel*

FOR several years the Committee on Training and Personnel has collected data concerning students registered in schools of public health and the public health degrees granted. The following is the report for the calendar year 1930.

TABLE I

NUMBER OF STUDENTS ENROLLED AND PUBLIC HEALTH DEGREES OFFERED AND CONFERRED IN 1930, IN COURSES REQUIRING AT LEAST ONE YEAR OF RESIDENCE AND LEADING TO A PUBLIC HEALTH DEGREE

School	Degrees	No. Enrolled 1929-1930	No. of Degrees Granted 1930

U. S. Public Health Station Opened in Mexico City

THE first office of the U. S. Public Health Service to be opened in Latin America has been established in Mexico City at the United States Consulate General under the direction of Dr. Howard Franklyn Smith (major U. S. M. C.), surgeon of the U. S. Public Health Service.

There are 29 similar offices in Europe at American consulates. These are located in districts which are sources of heavy immigration to the United States.

Tuberculosis Death Rates

FIGURES of the tuberculosis death rate compiled by Godias J. Drolet, New York Tuberculosis and Health Association, in 45 large cities for 1929-1930, show a total decrease of 7 per cent in the rate. Only 5 of the number show an increase, and of these, 3 are in the North, and 2 in the South. Very different is the story of the death rate among the colored in 39 large cities. Many of the northern cities had a marked increase for the colored race, New York leading in the increase in the total number of deaths, while Chicago showed a decrease. Memphis, Tenn., and Dallas, Tex., were the only southern cities, geographically, which had a marked increase. In some of the centrally located cities there was an increase in deaths; in others, a decrease. Indianapolis had a decrease of 22, and St. Louis, 17, while Washington, Baltimore, and Cincinnati had marked increases. Mr. Drolet says:

Between 1920 and 1928 the tuberculosis reduction among whites was 12 per cent in the southern cities, 38 per cent in the central cities, and 41 per cent in the northern cities.

Among the colored, deaths from tuberculosis in the 8 southern cities increased in 3 and were almost stationary or declining in the other 5, the net result being an increase from 1,250 to 1,308, namely, by 58 or 4 per cent; in the central cities the tuberculosis mortality among the colored declined in 3 and increased in 5 so that as a net result the mortality of 1920 rose from 1,492 to 1,596 in 1928, or by 6.5 per cent; in the 8 northern cities, in Pittsburgh there were 2 deaths less in 1928 than in 1920, and in all 7 others the mortality increased so that from 2,016 deaths among the colored in 1920 the total rose to 3,209 in 1928 or by 37 per cent. In other words, in the northern cities as against a decline in the number of tuberculosis deaths among whites of 41 per cent we have an increase among the colored of 37 per cent; in the 8 southern cities, the white tuberculosis mortality in its gross total was reduced by 12 per cent but that of the colored rose by 4 per cent.

The cause is not clear, though the tremendous emigration of Negroes from the South to the North, which has taken place during the last few years, probably has something to do with it. Certainly it has been accompanied by much suffering from tuberculosis and in some cities has greatly complicated the tuberculosis problem. However, it seems reasonably sure that when the census returns are available by race, it will be found that the death rate among the colored in northern cities for 1930 is lower than it was in 1920. In other words, in spite of some discouraging figures, there seems to be a distinct improvement in the tuberculosis situation.

EDITORIAL SECTION

Expressions of opinion and statements of supposed facts are published on authority of the writer under whose name they appear, and are not to be regarded as expressing the views of the American Public Health Association, unless such statements or opinions have been adopted by vote of the Association.

PUERPERAL FEVER

PUERPERAL fever continues to be a blot on the escutcheon of preventive medicine. For some years after the discoveries of Pasteur, it was often said that any physician who lost a case from puerperal fever was criminally responsible. Obstetricians in many countries are awake to the situation, and a good many propositions to avoid infection have been made and tried out. Digital diagnosis of the presentation is avoided by many, but in spite of our efforts, the death rate from puerperal fever still remains high. We have published one editorial on this subject,¹ suggesting that the presence of hemolytic streptococcus in the upper respiratory tract was a probable source of infection.

In Great Britain a number of studies have been made, the most recently published being those in the Hospital for Infectious Diseases of Aberdeen, Scotland. For 8 years, during which 221 cases of puerperal fever and 25 cases of septic abortion were admitted, bacteriological examinations, chiefly of the nose and throat of the attendants, were made, and the patients themselves more completely examined. In 221 cultures from the interior of the uterus, the hemolytic streptococcus was found 149 times, being the only organism present in 120 cases. Blood cultures were positive for this organism in 22.9 per cent of the cases, and only 3 per cent showed the presence of other organisms. It was present in 43 of 46 fatal cases.

In the cases of abortion, the *S. hemolyticus* was found in pure cul-

ture from the uterus in 11 cases. In 3, the *B. coli* was found. It was obtained in pure cultures in 15 of these uterine cultures, and in 12 the source was definitely the nose or throat of the physician, nurse, or student attendant. In one, the infection seemed to be autogenic, there being a focus of infection in the patient's hand. The 3 colon cases originated from the urinary tract or the intestine.

The suggestions made by the investigator and the Department of Health for Scotland, under whose auspices the publication was made, are the wearing of masks by physicians, midwives and nurses, and more careful preparation of the hands.

These studies have been carefully controlled and carry conviction. With our present knowledge of bacteriology and the wonderful advances made along most lines in this science, as well as its practical applications, it certainly seems that we should be able to prevent the maternal mortality which remains so high. Our showing in America is something of which we have no cause to be proud, and any suggestion which holds out the hope of improvement will doubtless be welcomed by practitioners engaged in this line of work.

UNPROFESSIONAL ADVERTISING

EVERY rose has its thorn. There is an army made up of earnest men and women, some well trained, and some not, conscientiously working for the betterment of health. This is the rose in the picture. The interest of the public in health has been seized upon by advertisers to exploit everything from tooth paste to corn cures, including those diseases which constitute the major tragedies of human life—cancer, tuberculosis, etc. This is the thorn in the picture.

Our newspapers are full of the most preposterous statements, and for some time, supposedly reputable physicians and health officers have lent their names to statements, many of which go beyond knowledge or facts. Not only have our American physicians been selling their names to advertisers, but foreigners have been brought in almost wholesale. In practically every case the advertisements state that these men are "noted," "famous," or "experts." Now and then they get hold of people who are actually well known, and who should know better than to lend themselves to such deception of the public.

The American Public Health Association has always stood against such practices. Within the past year members of the Association and some who have reached the dignity of Fellowship, and are even health

officers, have signed advertisements of various products. Feeling that this is a scandal affecting our honor, the following resolution amending the By-laws was passed by the Governing Council at the Annual Meeting in Fort Worth, October 30, 1930:

If, in the opinion of the Executive Board, any member or Fellow of the Association be found (hereafter) to have permitted the use of his name, or otherwise to have allowed himself to be quoted or used for illustration in the advertising of a commercial product, in such a manner as to reflect discredit upon the Association, his Fellowship or membership in the Association shall thereupon be terminated. The application of this article shall not be retroactive.

The enforcement of the provisions of this resolution lies with the Committee on Fellowship and Membership. The Executive Board of the Association has asked for the publication of the resolution. We therefore commend its careful study to those members and Fellows who have allowed themselves to engage in the practice condemned. We earnestly beg that those who have the honor of being members or Fellows of this Association refuse the use of their names in advertisements of any and every sort. One of the great functions of this Association is to instruct the public in matters of health. When a member sells his name for the exploitation of all sorts of products, he strikes a blow at the dignity of the profession to which he owes allegiance, and breaks down the confidence of the public in it.

THE LEONARD WOOD MEMORIAL CONFERENCE ON LEPROSY

THERE was held in Manila, January 9-23, 1931, an International Conference on Leprosy under the auspices of the Leonard Wood Memorial. Stress was laid on the importance of an international understanding among those studying the disease, since great confusion has existed concerning situations and practices. It was advised that leprosy workers be afforded opportunities of making study tours and be transferred from one region to another in order to study the peculiarities and conditions in other countries. Since the term "leper" carries social stigma, it was advised that the word be dropped, and the phrase "case of leprosy" be used.

The clinical classification recommended was: (a) neural, and (b) cutaneous, though it was recognized that it was a general disease seldom or never confined to one tissue. "Open" and "closed" cases were recognized chiefly with regard to administrative action. The lesions were classified and terms suggested for them, with the hope that standardization among writers and workers would result. Those

ulcers, due directly to the disease, which discharge leprosy bacilli are called "leprotic," while those caused indirectly are "trophic," as they are usually the result of destruction of the nerve. Special stress was laid on the importance of early diagnosis, since treatment is more successful than in later stages. The use of some form of the chaulmoogra group of oils or their derivatives was stressed.

An important point discussed was the decision of whether cases were active, quiescent, or arrested. The last term was suggested as being more conservative. In general, the terminology concerning leprosy was brought more into line with that of tuberculosis. Many suggestions were made concerning research and the particular lines which it should follow.

Perhaps the most important action was the formation of an International Leprosy Association, with Dr. Victor G. Heiser, President. It was decided also to publish a *Journal of Leprosy*, with Dr. H. W. Wade of the Culion Leper Colony as temporary Editor, assisted by Dr. Lie of Norway, and Dr. Maxwell of China.

A VALUABLE IDEA FROM JOHNS HOPKINS

THE recent action of the faculty of the School of Hygiene and Public Health of Johns Hopkins University is extremely significant to the teaching profession. The School of Public Health was founded through the efforts of Dr. William H. Welch and he was its first Director. He was succeeded by Dr. William H. Howell, a physiologist of world-wide reputation. His retirement in 1931 led to the necessity for some change and the selection of a new head for the school. The faculty showed its wisdom in selecting Dr. Wade H. Frost as its Dean, the office of Director having been abolished.

It seems that the faculty as a whole believed that the control of the school belonged properly to themselves. This is very different from the general practice in the schools of universities throughout the United States, since the faculty as a whole is not consulted, and the office of Dean goes only too often to some gumshoe politician or incompetent who has spent more time in toadying to the powers that be than in scientific work.

Really scientific men bent on research usually dislike administrative work, though some of them are forced into it by their prominence. This has been admirably expressed somewhat as follows: "When a man does notable scientific work, he is sterilized by being put in an executive position." The system in vogue in most institutions is not consistent with our ideas of democracy. Presidents occasionally want deans who have some ideas, but for the most part, they apparently

prefer men who will "go along," and support them in times of controversy.

At the Johns Hopkins School, a limit of three years has been fixed with the provision that the Dean cannot succeed himself. This has some excellent features, and some which are not so good, though it prevents the building up of cliques. A somewhat similar rule is in vogue in many scientific societies. In a school it means that the dean can return to his specialty within a few years and his election does not "sterilize" him for life. When a particularly good dean has been chosen, as is doubtless true in the case which has led to this discussion, there will naturally be regret when his term of service is over, though we cannot but approve of the fundamental idea and the spirit which has led to this change. We commend the action and its educational sanity to other institutions.

ASSOCIATION NEWS

SIXTIETH ANNUAL MEETING
AMERICAN PUBLIC HEALTH ASSOCIATION
Montreal—September 14-17
HEADQUARTERS—WINDSOR HOTEL

IN reply to a recent communication, more than 600 members of the Association have already expressed their intention to attend the Montreal Annual Meeting. Less than one-quarter of the total membership has been heard from, and if the same proportion holds throughout, the attendance will approximate 2,000, not including guests.

The Annual Meeting Program Committee has held two meetings, one with Section Secretaries. Aime Cousineau, Secretary of the Local Committee on Arrangements, has reported local progress in the organization of groups to plan entertainment, scientific trips, transportation, etc. Section Secretaries

have received more offers of papers than in previous years, and in several instances, section programs are already complete. Special sessions on Rural Sanitation, Health Education and Toxoid Immunization are being arranged. There is considerable interest in the contemplated session on British Public Health Administration and invitations have been issued to a number of British authorities to present papers.

A number of luncheon and dinner sessions are planned, notably a dinner tendered in honor of Dr. Alice Hamilton, by the Industrial Hygiene Section, and a joint dinner meeting of the Health Officers Section, the International So-

ciety of Medical Officers of Health, and the American Association of School Physicians. The Public Health Engineering Section will hold its usual dinner meeting with the Conference of State Sanitary Engineers. The annual Banquet will be held at the close of the meeting on Thursday evening.

The preliminary program will be published in the August *Journal*.

POST-CONVENTION TOUR TO QUEBEC AND THE SAGUENAY RIVER

A FOUR-DAY Annual Meeting with its multiplicity of sessions, speakers, luncheon and dinner meetings, and close application to business of the day is sufficiently tiring to mind and body to justify a brief vacation at its close.

Because of the proximity of Quebec to Montreal and the beautiful scenery to be viewed on the St. Lawrence and on the Saguenay Rivers, the Executive

Board has approved a 3-day, all-expense trip by steamer after the Montreal meeting. The S. S. St. Lawrence has been chartered for the occasion and will leave Montreal about midnight on Thursday, September 17. The following day will be spent in Quebec at the invitation of Dr. V. Martin, the Medical Officer of Health. The world-renowned shrine of St. Anne de Beaupre will be visited and Montmorency Falls. Saturday morning the steamer stops at Grosse Isle for an hour or two so that the Government Quarantine Station, under the direction of Dr. Pagé, may be inspected. Then follows a trip up the lovely Saguenay River. The return to Montreal will be made in daylight and delegates will arrive in time to board evening trains for home.

A detailed itinerary is in the mails at this time. Reservations may be made at once.

ANNUAL MEETING INFORMATION

REDUCED RAILROAD FARES

REDUCED railroad fares on the Identification Certificate Plan have been authorized by the several Passenger Associations in the United States and Canada, which will entitle all members and dependent members of their families to a special rate of a fare and one-half for the round trip to Montreal.

Under this plan an Identification Certificate *must be presented* to the ticket agent when purchasing tickets. (One will be mailed to every member of the Association about August 15.) This is the ticket agent's authority to issue to delegates and dependent members of their families a round-trip ticket to Montreal at the reduced rate. The routing should be specified when making the purchase, for the routing covered by the round-trip ticket cannot be changed at Montreal. All return tickets must be validated, before leaving Mont-

real, at the regular railroad ticket office. It is suggested that all members consult their local ticket agents in regard to dates of sale and return limit of reduced-rate tickets, as these limits vary according to distance from Montreal.

The Passenger Associations have authorized a special rate of fare and three-fifths for delegates who are taking the post-convention tour to the Saguenay, or who wish to return to their starting point by a different route. They should purchase tickets with return limit 30 days from date of sale.

Rates from principal centers on both bases are given herewith. Because summer tourist rates are less from some points than either fare and one-half or fare and three-fifths, a table of such rates is also included.

Fare and one-half, fare and three-fifths or summer tourist fare should be specified when purchasing tickets.

* Return trip may be made over different route.

† Summer Tourist Tickets will be sold from May 15 to and including September 30. Passengers using these tickets must return to starting point by October 31.

MAKE YOUR HOTEL RESERVATIONS NOW

MONTREAL is popular as a convention city. There is every indication even at this early date of a record attendance when the American Public Health Association and other affiliated societies meet there September 14-17.

The Windsor and the Mount Royal are the leading hotels. The Windsor is the headquarters hotel because of superior meeting hall facilities. Only a few hundred delegates can be accommodated at the Windsor. Single rooms

there are decidedly limited. If you plan to attend the Montreal sessions, and wish to stay at the headquarters hotel, it is suggested that you make arrangements with an associate to occupy a double room.

The Mount Royal is a short block from the Windsor and can supply either single or double room accommodations.

Room rates for both hotels are given below, together with rates for other good Montreal hotels.

Make your reservation now!

NEW MEMBERS

The following list includes applicants who have been approved for membership in the A. P. H. A. by the Sub-committee on Eligibility. These new members have requested affiliation with the sections indicated, and action by the Section Council will follow.

Health Officers Section

- Laura Arney, Elmwood Park, Ill., Commissioner of Health
 G. N. Bilby, M.D., Oklahoma City, Okla., State Health Commissioner
 C. M. Burchfiel, A.B., B.S., M.D., San Jose, Calif., Health Officer, Santa Clara County
 Jean P. Decarie, M.D., Montreal, P. Que., Inspector General, Provincial Bureau of Health
 Avery A. Drake, M.D., B.A., Flat River, Mo., Assistant Health Officer
 Milford G. Flath, Stanley, N. D., City Health Officer
 Will H. Moore, M.D., Valley City, N. D., City Health Officer
 Wilbur N. O'Brien, Ph.G., Ph.C., Newburyport, Mass., Agent, Board of Health
 Harry B. Torrey, Ph.D., M.D., Palo Alto, Calif., Professor of Hygiene and Physical Education

Laboratory Section

- J. A. Trent, M.A., Pittsburg, Kans., Assistant Professor, Biological Sciences

Public Health Engineering Section

- Rene Cyr, C.E., Montreal, P. Que., Assistant Sanitary Engineer, Provincial Bureau of Health
 Marc Gilbert, B.A., C.E., B.S.A., Montreal, P. Que., Secretary of Sanitary Engineer, Dept. of Health
 Adrien Plamondon, B.A., C.E., Montreal, P. Que., Consulting Engineer for Local Municipalities
 Leo B. Wood, Flat River, Mo., Sanitary Engineer, Dept. of Health

Industrial Hygiene Section

- Murl E. Fulk, B.S., A.B., A.M., M.D., Philo, O., Industrial Physician, Ohio Power Co.

Food, Drugs & Nutrition Section

- Lawrence W. Bass, Ph.D., New York, N. Y., Assistant Director of Research, Borden Co.
 Ray W. Clough, Ph.D., Seattle, Wash., Chemist and Bacteriologist, National Canners Assn.
 Ruben W. Hills, San Francisco, Calif. (Assoc.)

Child Hygiene Section

- Joseph B. Bloom, M.D., B.S., Pittsburgh, Pa., School Physician
 Myrnie A. Gifford, M.D., Berkeley, Calif., Field Physician, Bureau of Child Hygiene, State Dept. of Health
 Clare Terwilliger, A.B., R.N., New York, N. Y., Assistant Secretary, Murry & Leonie Guggenheim Dental Clinic

Public Health Education Section

- Clifford S. Thompson, M.D.C.M., Montreal, P. Que., Medical Officer, Steel Co. of Canada

Public Health Nursing Section

- Catharine S. Bastin, R.N., A.B., Portland, Ore., Assistant Professor of Applied Social Science and Nursing Education
 Clara B. Gould, P.H.N., San Jose, Calif., Supervising Nurse, Santa Clara County Health Dept.
 Edna M. Hardsaw, P.H.N., Charleston, W. Va., Supervisor of Public Health Nursing, State Dept. of Health
 Emma S. Maylor, Albuquerque, New Mex., Public Health Nurse, Bernalillo County Health Dept.
 Eunice T. Munson, R.N., Philippi, W. Va., School Nurse
 Sarah I. Richards, R.N., Jensen, Fla., Staff Nurse, State Board of Health
 Kathryn Schulken, R.N., Denver, Colo., Supt. Visiting Nurse Assn.
 Hortense P. Stafford, R.N., Carbondale, Ill., U. S. District Nurse (Assoc.)
 Helen M. Wolfe, Twin Falls, Idaho, Public Health Nurse, Health Unit

Epidemiology Section

- R. R. Parker, Ph.D., Hamilton, Mont., Special Expert, U. S. Public Health Service, Charge Rocky Mountain Spotted Fever Investigation

Unaffiliated

- Edward J. McKay, Woodside, L. I. (Assoc.)

DECEASED MEMBERS

- SAMUEL H. DURGIN, M.D., Allston, Mass., Elected Member 1875, Honorary Fellow 1922
 ALLEN HAZEN, New York, N. Y., Elected Member 1892, Fellow 1922
 THOMAS F. KENNEY, M.D., Worcester, Mass., Elected Member 1918, Fellow 1922
 V. A. MOORE, M.D., Ithaca, N. Y., Elected Member 1896, Fellow 1922
 R. A. MARTIN, M.D., Petersburg, Va., Elected Member 1919, Fellow 1923
 MARY ELIZABETH AYER, R.N., Northampton, Mass., Elected Member 1928
 WILLIAM H. BEATTY, New York, N. Y., Elected Member 1930 (Assoc.)
 H. T. G. NAUMANN, Port Huron, Mich., Elected Member 1917

PUBLIC HEALTH ADMINISTRATION

HENRY F. VAUGHAN, D. P. H.

EPIDEMIOLOGICAL MASTER CHART

GEORGE B. DARLING, JR.

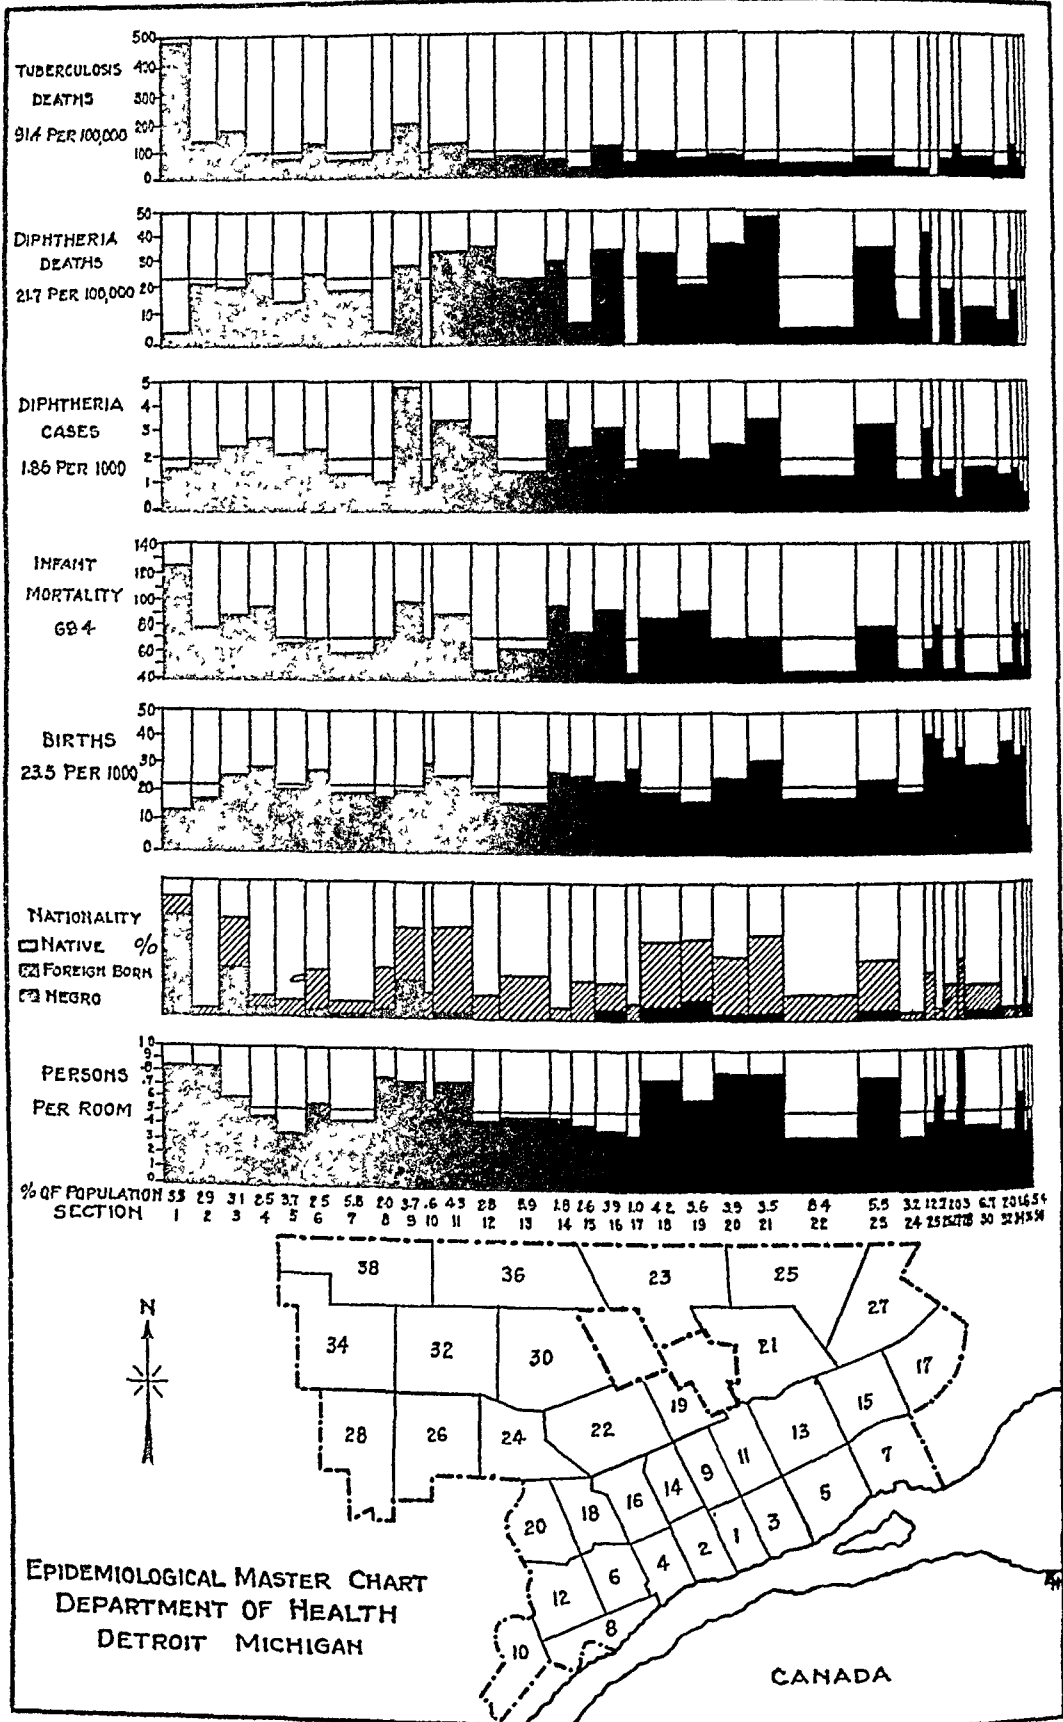

Assistant Epidemiologist, Department of Health, Detroit, Mich.

A NEED has long been felt for a simple graphical presentation of certain epidemiological data often correlated in analyses of public health problems. The need has been particularly acute in the supervision of large areas such as states or in the larger municipalities. For the statement of the problem, rates for the city or state have been sufficient; but for administrators faced with the necessity of attacking these problems at some definite point, it is essential that they be factored into their component parts. This is usually accomplished by division into districts. The common method has been to use maps and show by means of colors or different cross hatching the various degrees of the condition under analysis. The difficulties inherent in this type are familiar to all those who have used them. The necessity for many maps and the fallibility of visual perception lead to varying degrees of interpretation of the actual situation. Then, too, arbitrary groups must be assumed with limits defining the use of a particular color or cross hatching. Variations or trends within these artificial groups are lost entirely.

The master chart presented herewith has been very helpful in Detroit in analyzing the various problems indicated. It has been found particularly useful in two main fields—first, the intelligent planning of campaigns for the lowering of specific death rates; and

second, in explaining to the mayor and common council, and other interested lay groups, the reasons for certain activities and the necessity for continued financial support. For example, in the recent campaign for the eradication of diphtheria the chart clearly indicated those districts in which intensive house-to-house canvassing by nurses would be most helpful.

The principle of the chart is simple enough. The city (or state) is divided into sanitary districts. The necessary information is compiled by district. The map shows the geographical relationship of district to district. The bar is divided into as many parts as there are districts. The districts are laid off in numerical sequence, the width allotted on the base line being that per cent of the length of the bar that the population of that district is of the total population of the city. The horizontal line then represents the average rate for the city, and the rate for the district is indicated by the height of the bar. The scales used are those most convenient for the graphical presentation. The rates from district to district are easily compared by the height of the bars. At the same time the area of the bar shows in direct proportion the number of people affected by that rate. Thus it may be seen at a glance that a high rate in a certain district may affect a very much smaller number of people than a low rate in another district which may

as a consequence be of much greater significance in its effect on the rate of the city as a whole.

A word should be said about the bar on nationality. In the chart as it is used in Detroit the foreign born groups are divided into their major nationalities and indicated by various colors. The prohibitive cost of reproduction of the chart in that form for publication makes the demonstration of the value of this method impossible. It has been found extremely helpful however. For instance it will be seen from the chart that the districts with the highest diphtheria rates have the highest percentages of foreign born. It was found upon analysis that Polish was the highest single contributing nationality and was represented in its correct proportion by a yellow horizontal band. The advantage of this information to an administrator about to throw a large number of nurses in the field is obvious.

Correlation of the high tuberculosis death rates with high percentages of

colored population is easily seen as is the reverse relationship in regard to diphtheria rates.

The bar on density of population shows the worst crowding in a district with a relatively small number of people. If this is compared with the various morbidity and mortality rates for the district and also with the actual area as shown by the map the value of the chart is well illustrated.

Of course, in this reproduction the number of items has been limited but all of the information necessary to the adequate understanding of a city by its health officer may be so charted. The method has also been found very valuable in comparing the trend of a particular condition over a period of years. For this purpose the bars are used for intervals of time rather than for various items.

The epidemiological master chart is offered as a new tool in the statistical approach to the complex administrative problems of public health.

LABORATORY

JOHN F. NORTON, PH. D.

USE OF OCULISTS' LOUPE IN THE ISOLATION OF PURE BACTERIAL CULTURES

IVAN C. HALL, PH. D.

*Department of Bacteriology and Public Health, University of Colorado,
School of Medicine and Hospitals, Denver, Colo.*

THE successful isolation of pure cultures by the methods of Koch and Hesse depends, as is well known, upon securing a sufficient separation of the cells in or upon the medium to permit each to develop a new colony apart from other colonies. If two or more daughter cells cling together and form a single

colony, as in the case of the diplococci or the streptococci, it makes no difference whatever; all of the cells of the new colony have been derived from a single parent cell, and succeeding cultures transferred from such a colony will be pure, precisely as if a single cell had been transferred by a Barber pipette.

The principal error involved in cultural methods of isolation depends upon the possibility that occasionally two or more cells of different parentage may adhere and their progeny be represented together in the colony. If the associated species should happen to be of similar morphology or if one should greatly outgrow the other, the chance of detecting the impurity microscopically would be very slight. In isolating aerobic bacteria from agar plates one occasionally transfers obligate anaerobes whose presence is not at first detected, and in isolating anaerobic bacteria from deep agar one sometimes carries along a second species whose specialized requirements for growth were not met in the medium used, thus resulting in impure cultures. These contingencies fortunately are not very common; the first may be overcome easily by repeated aerobic transfers, the second, by the use of different kinds of mediums for successive isolations.

A much more common source of impurity in fished cultures is the adjacent growth of minute colonies that can be detected only by a meticulously critical microscopic examination. Surprisingly few of the recent textbooks emphasize this point although it is well covered and in essentially similar fashion by Zinsser's *Textbook of Bacteriology* (1929) and by Park and Williams' *Pathogenic Micro-organisms* (1929).

Quoting Zinsser, p. 143:

Cultures should never be fished under the naked eye, no matter how far apart and discrete they may appear, since not infrequently close to the edge of or just beneath a larger colony there may be a minute colony of another species which may be too small to be visible to the naked eye, but which, nevertheless, if touched by accident will contaminate the subculture.

For proper "fishing," the Petri plate with cover removed should be placed upon the stage of the microscope and examined with a low power objective, such as Leitz No. 2 or Zeiss AA. The sterilized platinum needle,

held in the right hand, is then carefully directed into the line of focus of the lens, while the small finger of the hand is steadied upon the edge of the microscope stage. When the

FIGURE I—Fishing aerobic colonies with the Hardy-Beebe Binocular Loupe

point of the needle is clearly visible through the microscope, it is gently depressed until it is seen to touch the colony and to carry away a portion of it. The needle is then withdrawn without again touching the nutrient medium or the edges of the glass or lens, and transferred to a tube of whatever medium is desired. In this way, individuals of one colony—descendants of a single bacterium of the original mixture—are carried over to the fresh medium.

This procedure is open to the objections that it unduly exposes the colonies to contamination from the air, and that it is difficult to guide the needle while looking through the compound microscope.

Dissecting microscopes, reading glasses, and engraver's monacles have been tried with indifferent success. For the last decade I have used a small Coddington lens (10x) for examining

and selecting colonies which were then picked with the naked eye, holding the dish slightly open for a moment in the left hand while manipulating the needle in the right. I believe this method is used widely, in spite of Zinsser's admonition to the contrary.

During the past year I have used the binocular Hardy-Beebe loupe¹ sold by the American Optical Company, with greatest satisfaction in picking colonies after they have been first inspected and selected by means of the hand lens. If such a loupe has ever been advocated for bacteriological work, I have been unable to find any reference to it in a careful search of the literature.

Its advantages are obvious. The milled adjustment of the width between the anterior lenses facilitates exact duplication of the binocular images. If one wears glasses he may have his own lenses inserted in the frames or the loupe may be worn over his own spectacles. The great advantage of switching instantly from the loupe to ordinary vision and back again, with the hands entirely free to manipulate plate or tube cultures and planting wires, must be experienced to be appreciated. The use

of the loupe is illustrated herewith (Figure I).

In isolating aerobic bacteria, it is our practice to streak from liquid cultures or suspensions upon half the surface of prepared plain, blood, or eosin-methylene blue plates, leaving the other half untouched as a control upon the sterility of the medium. Confluent colonies generally appear upon that portion first streaked while well separated colonies usually appear near the center of the plate. These are fished under the loupe to the unused surface and after incubation examined microscopically for purity. This plan effects a great saving of culture media and time as compared with the commonly used method of plating out serial dilutions in agar.

The loupe is used similarly in the isolation of anaerobic bacteria grown as separate colonies in Burri tubes, from which the agar cylinders have been pushed out into sterile Petri dishes and sliced as described in a previous paper.²

A RAPID METHOD OF TYPING PNEUMOCOCCI

MILTON H. BROWN, M. D.

*Research Associate, Connaught Laboratories, University of Toronto,
Toronto, Ont.*

THE first requisite in the serum treatment of pneumonia is the determination of the type of the invading pneumococcus. The value of early administration of serum is one of the dominant factors being stressed today; hence it is all the more imperative that the particular type of pneumococcus should be determined at the earliest moment.

Neufeld demonstrated as early as 1902 that on mixing pneumococci and

serum from animals previously inoculated with the homologous strain and examining microscopically, agglutination was seen to occur. Recently Sabin has made certain modifications of this procedure, so that a rapid and very reliable method is available.

The procedure is much as follows:

1. A representative sample of sputum should be obtained, if necessary, waiting until the patient expectorates material directly from the bronchial tract in-

stead of saliva or pharyngeal secretions. A surprisingly small amount of actual sputum is necessary. The sample should be obtained in a clean sterile container, free from any preservative.

2. Wash the sputum at least three times by swirling the mass of sputum around in sterile saline contained in three separate Petri dishes. This tends to remove extraneous microorganisms. Following this, the sputum is thoroughly emulsified in saline, and in order to facilitate this, a 5 c.c. syringe and a needle of large caliber are very useful. At least 1 c.c. of emulsified sputum is then injected intraperitoneally into a mouse, using a needle of small caliber. As a matter of routine, two mice are injected.

3. In 3 hours a peritoneal puncture is performed, using a capillary pipette made by drawing out a piece of small glass tubing in a flame. The finer the pipette, the more satisfactory it is for this purpose. Grasp the mouse by the loose skin of the neck between the thumb and index finger, with the back of the mouse across the palmar surface of the hand, and made secure by looping the tail between the ring and little fingers. The abdomen of the mouse being thus well exposed, the capillary pipette is passed into the peritoneal cavity, and by capillary traction fluid will be seen extending into the pipette. The pipette is then removed and the mouse is kept for further observation.

4. The surface of a well cleaned glass slide is divided into four sections, using a glass pencil. On each of these four sections is placed a small drop of the peritoneal exudate from the pipette. With the first of the four drops of peritoneal exudate is mixed a drop of saline which is then spread thinly and allowed to dry. To the second drop of the exudate, a drop of Type I agglutinating serum diluted 1 in 10 is added and the mixture is spread thinly and allowed to dry. Similarly, the third

drop of exudate is mixed with a drop of Type II agglutinating serum, diluted 1 in 10, and is spread thinly and allowed to dry, and to the last drop of exudate a drop of Type III agglutinating serum, diluted 1 in 5, is added and the mixture is spread thinly and allowed to dry. The films are then fixed by passing the slide two or three times over a moderate flame. (For convenience one usually labels each of the above four sections as Sal., I, II, III with red pencil.)

5. The slide is then stained for 1 minute with basic fuchsin stain. The stain, which should be fresh, is made by adding 10 c.c. of a saturated alcoholic solution of basic fuchsin to 90 c.c. of distilled water, and filtering through paper. (The saturated alcoholic solution is made by adding 10 g. of basic fuchsin to 100 c.c. of absolute alcohol.) Other stains such as methyl violet may be used, but basic fuchsin has been found to be the most satisfactory. Wash off the stain gently with water, blot dry and examine under an oil immersion lens. The saline suspension is examined first and serves as a control. The character of the microorganisms is then determined. Frequently a pure culture of a lance-shaped diplococcus is found. The other sections are examined in sequence, and definite clumping of lance-shaped diplococci in one of the sections serves to denote the type. There may be many clumps consisting of only a few organisms or a few large clumps covering several microscopic fields. In examining for clumps one should not be misled by microorganisms, such as Gram-negative cocci, which tend to occur in clumps, or the grape-like clumps of staphylococci. These may be distinguished by being round or coccoid in shape in contrast to the lance-shaped diplococcus of pneumonia. The so-called capsule may be quite marked, especially in animal exudates such as obtained from the peritoneum of the mouse. Type III pneumococci usually

show very marked capsules, often so much so that the organisms themselves are seen with difficulty and the clumps are not usually packed so tightly together as are Type I or Type II organisms. Further, in a clump of Type III pneumococci one may see a very fine thread-like matrix extending from organism to organism.

Usually the sputum is well digested in the peritoneal cavity of the mouse within 3 hours, especially in Type III cases, but occasionally one may be required to repeat the peritoneal puncture after a lapse of 4 or even 6 hours in order to obtain a satisfactory result. In our experience a sputum in which a satisfactory typing was not obtained after 6 hours was either free of a fixed type of pneumococcus or contained some other organism such as a streptococcus.

6. The mouse almost invariably survives the peritoneal puncture, but, if the organism is virulent, the mouse dies in from 18 to 24 hours. The peritoneum is then opened under aseptic precautions and the contents are washed out with 3 to 4 c.c. of saline. The washings are centrifuged, first at very low speed in order to throw down any blood cells. The supernatant fluid is drawn off and centrifuged at high speed to throw down the microorganisms.

A "ring test" or precipitin test is performed by floating about 0.1 c.c. of the supernatant over an equal quantity of agglutinating serum, diluted 1 in 10.

At the point of contact of serum and fluid a fluffy white ring appears almost immediately in the tube containing the serum of the corresponding type. The standard macroscopic agglutination test may be made with the centrifuged sediment. The latter two tests serve as a check on the rapid method, but in our experience the "ring test" is more readily and accurately interpreted. A broth culture may be made from the heart's blood of the mouse for purposes of further examination, and usually a pure culture of the pneumococcus is obtained from this source.

In a very early case of pneumonia, the first strain isolated may not be one of the fixed types so that it is often advisable to obtain another sample of sputum and repeat the search. In this way a Type I, II or III, which otherwise would have been missed, may be obtained.

We have found the rapid method of typing very satisfactory in the examination of spinal fluid, pleural exudate or blood cultures. Usually by proceeding directly with the material at hand instead of injecting a mouse, the type may be determined. If there are not sufficient organisms present, centrifuge the material and resuspend in a small amount of the supernatant. Failing either of these methods, one should inject the material into the peritoneal cavity of a mouse and proceed as with sputum.

VITAL STATISTICS

LOUIS I. DUBLIN, PH. D.

Vital Statistics for Scotland—1930—According to provisional figures reported by the Registrar-General for Scotland, the birth rate in 1930 was 19.3 per 1,000, which is 0.3 more than that of the previous year, but 0.9 less than that of the preceding 5 years, and 2.9 less than that of the preceding 10 years. The marriage rate was 6.8 per 1,000, which is the same as that for the previous year, and 0.2 more than the average of the preceding 5 years. The death rate was 13.2, which is 1.3 below the rate for 1929, 0.3 lower than the average of the preceding 5 years, and 0.6 lower than that for the preceding 10 years. The infant mortality rate for 1930 was 83 per 1,000 births, which is 4 less than that of 1929 and 7 less than the average of the preceding 10 years.

The death rate from all forms of tuberculosis, the lowest rate yet recorded for tuberculosis in Scotland, was 88 per 100,000 in 1930. It is 6 less than that for 1929 and 22 below the average of the past 10 years. The death rate from respiratory tuberculosis also reached a new low level in 1930, being 62 per 100,000, which is 5 less than in 1929 and 14 below the average of the past 10 years. Deaths from cancer numbered 7,120, which number shows an increase of 271 above the average for the preceding 5 years, and 622 above that for the previous 10 years.—*Med. Off.*, 45: 120 (Mar. 14), 1931.

Increase in Lung Cancer in Hamburg, Germany—Reports from the St. George Hospital in Hamburg indicate that since 1924 there has been in that region a notable increase in the fre-

quency of primary cancer of the lung. From 1911 to 1923, primary cancer of the lung constituted 0.36 per cent of all necropsies; during the 7-year period 1924 to 1930 the proportion rose to 1.06 per cent of all necropsies. The 50 to 60 and the 60 to 70 age groups were especially affected. The incidence among males is about three times as great as that among females. Among the causes of the increased incidence is the present higher average age of the population. More persons than formerly enter the cancer age. In addition to constitution, hereditary predisposition and trauma, chronic inflammatory irritants of all kinds may be incriminated, among which, besides influenza, may be mentioned especially the inspiration of dust and the exhaust gases of automobiles, more particularly of the heavy-oil motors.—*J. A. M. A.*, 96: 1328 (Apr. 18), 1931.

Public Health Progress in the Philippines during 1929—There seems to be some difficulty in the Philippine Islands in obtaining reliable health statistics, as the figures given in this article are all followed by the words "estimated" or "incomplete." The death rate for 1929 was 22.18, which is higher by 1.17 than the average rate for the past 5 years. The infant mortality rate was 165.03, against 154.02, the average for the past 5 years. The increase in the mortality was mostly from respiratory diseases, which were 5,118 in excess of the previous year: beriberi, diarrhea and enteritis, tuberculosis and dysentery also showed increases. There was a reduction in typhoid fever and

the mortality was the lowest recorded for this disease. Only 1 case of cholera occurred and it may therefore be said that the Philippine Islands have been free from outbreaks of cholera since 1926. Continuous anti-cholera vaccination of the masses is perhaps the factor most responsible for this satisfactory state of things. Only a few cases of smallpox occurred.

Vaccination is carried out very systematically and extensively, except in the non-Christian regions where great opposition by the natives is met with. Cerebrospinal meningitis never attained an epidemic character during the year: there were only 12 cases with 6 deaths from the disease in the City of Manila and 16 cases with 13 deaths in the provinces. As a number of Filipinos developed this disease on board ship on their way to Hawaii or the west coast of the United States special search was made for carriers among the general population and Filipinos going abroad. Only 0.9 per cent of over 10,000 examined were found positive. Tuberculosis caused over 30,000 deaths, equal to 12 per cent of the deaths. The mortality from malaria has been reduced to about a half of what it was in 1926. There were, at the end of 1929, 6,494 lepers under segregation and 1,321 new cases were isolated during the year. Patients are now presenting themselves for treatment in the early stages. Since 1922, 2,013 leprosy patients have been rendered negative and released. Prophylactic inoculations against smallpox, typhoid and paratyphoid, dysentery and cholera were performed as routine measures for the prevention of these diseases.—E. D. Aguilar, *J. Philippine Is. M. Dis.*, 10: 190–202, 1930. Abstr. by A. J. Collis, *Bull. Hyg.*, 6: 147–148 (Feb.), 1931.

Vital Statistics of Rio de Janeiro
—During the year 1929, there were 8,830 marriages and 39,042 births (of

which 36,188 were live births and 2,854 stillbirths) in the Federal District of Brazil. In the same year, 25,955 deaths occurred (that is, a coefficient of 15 per 1,000 of population). The still-born rate, which was diminishing from 1920 to 1923, began to rise again from 1923 to 1929. The outgoing and incoming of persons to Rio de Janeiro gave a deficit of 26,109 inhabitants, which may be attributed to the presence of yellow fever at Rio de Janeiro. The population of the city was estimated in 1927 as 1,729,299 inhabitants, which number seems to be quite correct unless the next census proves the opposite. The Yellow Fever Commission listed 198,000 houses. Knowing the shortage of houses and that all of them are usually overcrowded, it may be considered as an average of 10 persons per house, which gives a total population of 1,980,000.—*J. A. M. A.*, 96: 1164 (Apr. 4), 1931.

Vital Statistics for Indiana in 1930—A preliminary report of the Vital Statistics Division of the State Board of Health in Indiana for the calendar year 1930 shows a decrease in deaths and in death rates from practically all communicable diseases. While the figures are subject to slight change, they are essentially accurate. The total number of births for 1930 was 58,971—a rate of 18.2, which represents a decrease of 0.2 below that of 1929 and 0.9 below that of 1928. The total deaths were 39,061—a rate of 12.1, which represents a decrease of 0.7 below that of 1929 and 1928.

The death rate for infants under 1 year of age was 57.7 for 1930, the lowest yet recorded for the state, and it shows a decrease of 5.9 below that of 1929 and 4.7 below that of 1928. Deaths of mothers from maternal causes show a rate of 5.5 as against 6.8 in 1929 and 6.0 in 1928. The death rates 65.9 for tuberculosis, 3.3 for typhoid

fever, 4.1 for diphtheria, 2.1 for scarlet fever, 1.8 for measles, 3.0 for whooping cough and 2.9 for puerperal septicemia are the lowest rates ever recorded in Indiana for these diseases.—*Month. Bull., Indiana State Board of Health*, 34: 201 (Jan.), 1931.

Fewer Women than Men in Japan—According to the general census taken October 1, 1930, and published by the government, December 8, the population of Japan proper is 64,447,724, comprising 32,388,369 males and 32,059,355 females, which is nearly double the population in 1872, 59 years ago. According to the Committee for the Investigation of Population and Food Problems, it is estimated that the population of Japan proper will grow to almost 90,340,000 in the next 30 years.

As to the population, it is strange to find that the number of males exceeds by 329,014 the number of females, 101 males to 100 females. Tokyo has the highest ratio of males to females, 111.9 to 100; next comes Hokkaido, 109.3; then Osaka, 108.9. In large cities and the mining and planting districts, the number of males is greater, while females are more numerous in places with many spinning factories. The smaller number of females is said to be due to the fact that many females die young. Dr. T. Nagai, specialist on problems of population, has published his opinion that Japanese mothers are apt to have another baby soon after they have lost their children.—*J. A. M. A.*, 96: 879 (Mar. 14), 1931.

Fatal Accidents in Old Age—The problem of fatal accidents is concentrated largely among children and old people. Two out of every 5 accidental deaths occur among those who are under 15 years or who have reached 65 years. Relatively few of these deaths are of occupational origin. They oc-

cur, almost entirely, in the home, on the streets or in other "public places"—among the old, mostly in the home.

Falls are by far the most important type of fatal accident among elderly persons. In fact, more old people lose their lives through falls than in all other forms of accident combined. The statistics for many years confirm this. They show, further, that falls cause about three times as many deaths every year as does the type of accident next in importance among old people, namely, automobile fatalities. Falls and automobile casualties combined cause every year more than two-thirds of all the fatal accidents among people who have passed age 65.

We may, therefore, discuss with profit the circumstances that underlie these two types of fatal accidents among old persons.

Fatal falls among the old occur, for the most part, in or about the home. About one-half of these fatalities are due to falling down stairs; and tripping over rugs or carpets, falling off or over chairs and falling in bathtubs are of no small importance. Such accidents, when they happen to younger persons, are not apt to terminate fatally; but in old age any sort of injury, including the shocks arising from fractures, dislocations, multiple contusions, or even lesser injuries, often hasten death, even if they are not primary causes.

What can be done to check the rising death rate from falls among elderly persons? It should be remembered that the elderly woman is a more frequent victim than the elderly man. Home safety, then, should be taught by women's organizations. This, in fact, is now being done by the General Federation of Women's Clubs in several states, notably, Illinois, Pennsylvania, and North Carolina.

The majority of the falls among both elderly men and women would never occur if a little more care and fore-

thought were exercised. Sane precautions are called for to see that homes are kept in such order as to minimize the danger of falls. Many fatal falls are traceable to poor illumination, loose, broken, or badly spaced treads, or to obstructions left on stairways. The combination of highly polished floors and small rugs is particularly dangerous.

One death out of every 7 in automobile accidents is that of an elderly person. This ratio bids fair to become higher. Automobile fatalities have become the foremost of all safety problems at all times of life, and much attention has been directed toward their control as they affect childhood. As a result we appear to have achieved a slight decrease in deaths among children. But (although little emphasis has ever been placed upon the fact) the actual death rate from automobile accidents is higher in old age than in childhood—and the increase is still going on.

There are other types of fatal accidents prominent in old age. More than one-fifth of the accidental asphyxiations by gas affect old people; one-eighth of the fatal burns; one-sixth of the accidents due to cutting and piercing instruments; one-fifth of those due to street-cars and horse-drawn vehicles; over one-fifth of the deaths due to injuries by animals; two-fifths of those caused by excessive cold; and one-quarter of those due to excessive heat.

On the other hand, it is relatively seldom that old people die of accidental poisoning by solid or liquid substances; very few are drowned, shoot themselves accidentally, or are killed by lightning. Among the deaths due to occupational hazards, such as mining, quarry or machinery accidents, elderly people seldom figure because few are exposed to these risks. Deaths in airplane and balloon accidents are almost nil.—*Stat. Bull., Met. Life Ins. Co., Mar., 1931.*

PUBLIC HEALTH ENGINEERING

ARTHUR P. MILLER, C. E.

PROGRESS IN THE ENFORCEMENT OF THE NEW YORK STATE MILK CODE *

C. A. HOLMQUIST, F. A. P. H. A., AND W. D. TIEDEMAN, M. C. E.

*Director, Division of Sanitation, and Chief, Bureau of Milk Sanitation,
New York State Department of Health, Albany, N. Y.*

IN New York the so-called "State Milk Code" constitutes Chapter III of the State Sanitary Code. It has the "effect of law" and is effective throughout the state excepting in New York City. It was first enacted in 1914 and was in general modeled after a code which had then been in effect in New York City for several years. The state code was generally revised in 1928 and the New York City Code a little later and, in the revision and following numerous conferences, the more essential requirements in the two were made practically uniform. In July, 1930, the state code was further amended, chiefly by the addition of more detailed and definite requirements relating to cream. The milk regulations are, therefore, uniform throughout the state, except for minor differences between the state and New York City Codes, and except as other cities, acting under authority given them by law, have enacted more stringent requirements, not inconsistent with those of the state code.

Substantial progress in milk control was made in the cities, and some, but decidedly less, in the villages and rural communities during the 14-year period

following the enactment of the original code. The enforcement of the code is the responsibility of the health officer of each city, town or village. Practically all of the health officers in villages and towns were part-time officials with little if any training in milk control work and, except in a few instances, without expert assistance. It is not surprising that there should be considerable variation in the degree of enforcement in different places. There are, however, many instances in which health officers of smaller communities have made a hobby of milk control which has resulted in giving some of these small municipalities as good or better milk supplies than some of the larger cities.

For a period of nearly 2 years previous to the general revision of the code and before it became effective in 1928, a committee appointed by the public health council and headed by Dr. Paul B. Brooks, Deputy Commissioner, made an exhaustive study of milk control, and called into consultation health officials, milk producers, and milk distributors to determine the necessity for and practicability of the various requirements to be included in the code. An effort was made to eliminate provisions of the original code which had no marked public health significance. Before the code went into effect, an inten-

* Read at a Joint Session of the Public Health Engineering and the Food, Drugs and Nutrition Sections of the American Public Health Association at the Fifty-ninth Annual Meeting at Fort Worth, Tex., October 30, 1930.

sive educational campaign was carried on. Thousands of copies of the code were distributed and its provisions were discussed at numerous meetings attended by health officers, and milk producers and distributors.

An advisory committee made up of men representing the New York State Department of Agriculture and Markets, the State Agricultural College, the Geneva Experiment Station, large and small dealers and the producers, was appointed for the purposes of considering special problems that might arise as a result of the enforcement of the code and of promoting coöperation. This committee has been very helpful.

One of the important amendments of the milk code, made in 1928, provided for abandoning the old system of numerically scoring dairies in the grading of milk and basing grading chiefly upon bacterial examination of the milk. To make this provision effective, it became necessary to stimulate the development of laboratories in certain sections of the state. Through establishment of new laboratories or extension of the service of existing laboratories, laboratory facilities were made available to every health officer in the state. Taking advantage of a statute making this possible, the state has stimulated the development of county and municipal laboratories by paying half the cost of operating them when prescribed standards have been met.

Under another law, state aid is available to counties establishing county health departments and also to counties employing full-time county milk inspectors. This aid has contributed to improvement in milk control work, especially in the smaller communities in 7 counties. Four of these now have county health departments, 2 others have county milk inspectors, and another contracts with a commercial laboratory to do its milk laboratory and inspection work. Constant efforts are

being made to encourage the development of additional county units and the employment of county milk inspectors. Progress along this line is expected.

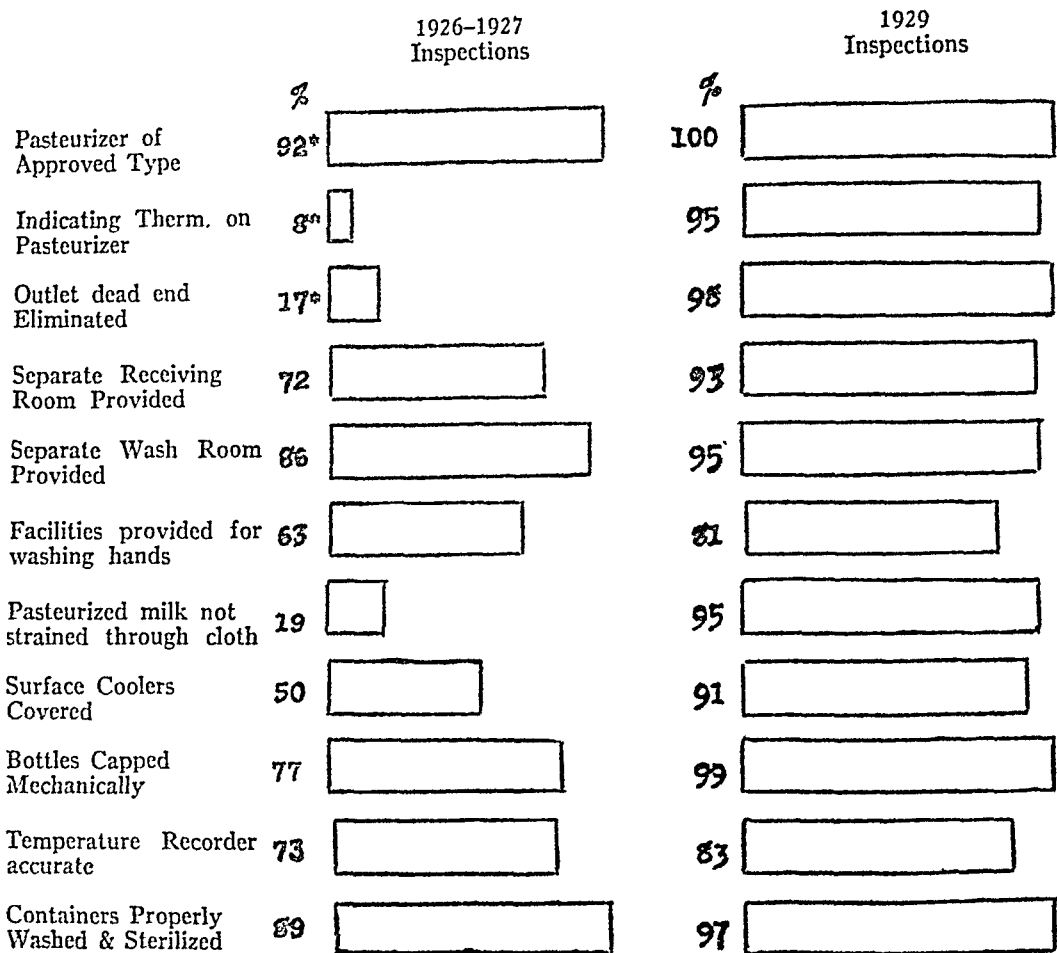

The code revisions effective in 1928 also included a general tightening up on the pasteurization requirements. The approval by the state commissioner of health of all pasteurizing apparatus as to type was required and also his approval in writing as to apparatus and efficiency of all plants producing pasteurized Grade A milk. Pasteurization was so defined as to require that *every particle* of milk be subjected to a temperature of 143° F. or more for not less than 30 minutes, whereas the original code required that milk be subjected to a temperature of 142 to 145° F. for not less than 30 minutes. A general revision was also made of pasteurizing plant regulations which are enacted by the commissioner as authorized by the code and are supplementary to the sanitary code.

Previous to 1928 the State Department of Health had had 2 men on milk control work attempting to cover an area of more than 47,000 square miles and the milk supply of more than 5 million people. Their efforts were necessarily limited. It was felt that the greatest good could be accomplished by devoting their time to inspecting pasteurizing plants and advising health officers as to their proper equipment, as to the efficiency of their operation and at the same time stimulating health officers to maintain standards and demand improvement.

Very soon after the revised code became effective, the milk control force was increased from 2 to 5 men. During the following year most pasteurizing plants were inspected twice instead of once and some that needed inspection most were visited three or four times during the year in order to secure the necessary improvements. In addition many tests of pasteurizers were made to

FIGURE I

* Not a legal requirement in 1926-27.

determine their efficiency. Continuous flow, in-the-bottle and pocket type pasteurizers were tested for temperature during the holding period by means of thermocouples and the holding periods were checked by timing or color tests. The results of this work were very gratifying. The accompanying chart (Figure I) shows a comparison of the percentage of compliance with some of the more important regulations just before the amendments went into effect and after they had been in effect about a year.

All pasteurizing equipment which could not be satisfactorily remodeled is

reported as of unapproved type. The 22 plants having such apparatus all installed new pasteurizers of satisfactory type. The equipment of pasteurizers with indicating thermometers was a new requirement and almost complete compliance was promptly secured. The 5 per cent non-compliance represents for the most part plants that had secured indicating thermometers which were found broken upon later inspection. These were promptly replaced with new thermometers. Pasteurizers which formerly had outlet dead ends were either replaced with new equipment or, where practicable, satisfactory flush or

close coupled leak protector outlet valves with sterilizing connections were installed. Leaking inlet valves were replaced by leak protector valves. As indicated by Figure I, other important improvements were made.

One very gratifying result of this work has been the increase in the consumption of pasteurized milk in the state. Between January 1, 1928, and January 1, 1929, the number of pasteurizing plants under our inspection increased from 518 to 646. This increase in the number of pasteurizing plants and a general increase in the amount of pasteurized milk sold by other plants gave a small but marked increase in the percentage of pasteurized milk consumed. We believe that to increase the proportion of properly pasteurized milk consumed as compared with raw milk is one of the most important accomplishments of any milk control program from the public health standpoint.

In addition to the progress made in increasing the efficiency of pasteurization and the use of pasteurized milk, material progress has been made in improving the quality of raw milk. The amended regulations eliminated Grade C milk and made Grade B raw milk a temporary grade which could be sold only in the interval between making official application for a tuberculin test and obtaining the test. Fixing the maximum bacteria count of raw milk at 30,000 and at the same time requiring that bacteria counts be made the basis for grading have materially improved the quality of raw milk.

A thorough investigation of certified milk production was also made last year. This survey showed that certified milk producers generally were making an honest effort to meet requirements. County Medical Milk Commissions formerly were not under health department supervision and many commissions were found to be very lax in the performance of

their duties. The amended New York State Code requires that each county medical milk commission shall make a monthly report upon its activities to the state department of health. The department has insisted that these reports be submitted regularly for checking so that there is assurance that important safeguards such as veterinary examination of cows, tuberculin tests and medical examination of milk handlers are being applied.

A conference between the Governor's Agricultural Advisory Committee, the State Department of Health, health officials of various communities throughout the state, and representatives of the milk producers and distributors was held early this year to discuss milk control. As a result a law was passed specifically charging the state commissioner of health with the duty of protecting and promoting the health and welfare of the people of New York State by inspecting, regulating and supervising the sanitary quality of milk and cream distributed, consumed or sold within the state, whether produced within or without the state. This law also provided funds for adding 11 milk control specialists to the department staff and for purchasing and equipping two mobile milk laboratories in addition to other necessary equipment. This law specifically provided that the department

... make a complete investigation, study and survey within and without the state, to determine, among other things, the following: (a) the present sources of supply of milk and cream for household consumption and for manufacturing purposes and the amount produced by such sources; (b) the adequacy of existing state and municipal machinery for the enforcement of sanitary regulations and the extent to which impurities have escaped detection and prevention; (c) the proper state or local agencies or combination of agencies to be entrusted with the duties and responsibilities of effective sanitary control and inspection of milk and cream in their various local and state-wide phases; (d) the probable cost to the state of adequately enforcing the rules

and regulations of the commissioner and the public health council; and (e) such other information relative or pertinent to the functions of such Bureau [of Milk Sanitation] as the commissioner may request.

The public health council, which is the body charged with enacting the provisions of the sanitary code, enacted further amendments to the code this year as indicated hereinbefore. These amendments were designed to raise further the standards of milk and cream in so far as the experience of the past 2 years indicated that it was practicable to do so, and completely revised the cream regulations providing for the grading thereof. The regulation covering the sale of milk and cream shipped into New York State was also revised to make it necessary to produce and handle such milk or cream in conformity to the requirements of the New York State milk code and to subject it to the same standards of supervision and inspection as are required for milk or cream produced within the state.

Among the regulations which were increased in stringency is one requiring that health officers may not issue permits for the sale of pasteurized milk or cream until

... officially notified that the plant in which such milk or cream is pasteurized has been inspected as to apparatus, sanitary conditions and efficiency of operation by an authorized representative of the State Department of Health and that in these respects at the time of inspection the conditions found were such as to warrant issuance of a permit.

A new regulation relating to mastitis was inserted in the milk code providing that producers immediately report inflamed conditions of the udders or teats

of cows and exclude the milk from such cows. These regulations were enacted May 19, 1930, and became effective July 1, 1930.

Considerable time has been consumed in organizing the new staff and in securing and equipping the two mobile laboratories. This work has, however, now been completed and the laboratories are in operation in the field surveying the milk supply of the state. The schedule under which they are working will make it possible to cover the state by the middle of December, 1930.

In summarizing the progress made in the enforcement of the New York State milk code, we can say (1) that marked improvement has been made in milk control in most New York State cities; (2) that the employment of county milk inspectors is being stimulated by offering state aid and is tending to materially improve enforcement work in the smaller communities; (3) that grading of milk chiefly on the basis of bacteria counts has done much to increase the quality of the raw milk supply; (4) that the checking of monthly reports of county medical milk commissions has improved the status of certified milk; (5) that the improvements made in pasteurizing plant equipment and in methods of operation taken together with the increase in the consumption of pasteurized milk represent valuable public health protection; and (6) that the increase in the state appropriation for milk control work has made it possible to devote more attention to the work of advising, supervising and stimulating the milk enforcement work of local health officials, which should mean still more progress in the near future.

INDUSTRIAL HYGIENE

EMERY R. HAYHURST, M. D., PH. D., AND LEONARD GREENBURG,
M. D., PH. D.

Carbon Monoxide Poisoning in Industry—Winslow takes the position that carbon monoxide ranks first, and lead second, among the industrial poisons. The Bureau of Industrial Hygiene, in this study, has directed its attention primarily to the effects of prolonged exposure to relatively low concentration of the gas rather than to acute asphyxia. The examination of a representative number of workers constantly exposed and a review of the voluminous literature of the subject constitute the main purposes of the present investigation.

In connection with carbon monoxide poisoning, the physiology, pathology, symptoms, diagnosis, and prognosis, comprise Part I with a discussion of 80 pages, including several tables. The carbon monoxide hazards in industry comprise Part II, which discusses sources, control of the use of gas heated appliances, the operation of the internal combustion engine, and the matter of compensation (some 60 pages). Part III, entitled "Medical Control of the Carbon Monoxide Hazard," is concerned with the physical examination of 50 garage workers, the medical supervision of workers, and the treatment of acute cases of carbon monoxide asphyxia (about 55 pages). There follows a valuable Appendix in which the methods for the detection of carbon monoxide in the air and in the blood, the gas masks, and forms for recording histories and examinations, are delineated. There is a Bibliography of 182 grouped references, of which 139 are upon carbon monoxide and the balance upon ozone. Some 26

tables, 8 charts, and 29 illustrations accompany.

Of value, particularly, is the discussion on exposure to low concentrations of the gas over considerable periods of time, as well as case histories and the control of the hazards in industrial process. Compensation procedure is illustrated by case citations and a classification of different forms of death claims. Table XIV, which is an infold, groups the symptoms, physical findings, and blood findings of 50 garage workers. The illustrations are of a rather new type in connection with the descriptions of carbon monoxide poisoning and of distinct educational value.—May R. Mayers, M.D., Bureau of Industrial Hygiene, New York State Department of Labor, *Special Bull.*, 1930, 243 pp.
E. R. H.

Claims Filed for Occupational Diseases, Ohio, 1927-1929—In 37 pages of tables are given the experiences of the Industrial Commission of Ohio with regard to occupational disease claims and their compensations during the 3-year period, 1927-1929. The tables are classified by industry, by types of diseases, by days lost, by compensation cost, by medical cost, with a separate grouping for claims disallowed with the nature of the diseases concerned.

There was a total of 3,229 claims filed, of which 561 were found non-compensable. The total includes 70 fatal claims, of which 52 were non-compensable, leaving 18 claims which were considered compensable. Of these, 15 were
